It is easy in this case also to find some reasonable explanation for the popular belief. Those who see many cases of obviously congenital mental defect in children know how reluctant even educated parents are to admit the possibility of the child having been born otherwise than healthy. A mother will hardly admit, even to herself, the slightest defect in her child's intellect for many months, and even then she believes that it has only just appeared and will assure the physician that it was "a beautiful baby born," but that "since it was vaccinated," had a fall, a fright, or what not, "it has not seemed the same child." In a country where belief in witches and changelings is firmly established, what is more natural than for the mother to snatch at the belief that some trick has been played by the fairies, and that her healthy child has been carried off and an idiotic substitute left? Were this all, no one would care to disturb so comforting a delusion, but, unfortunately, the result of these beliefs in "possession" and "changelings" has been to introduce most barbarous methods of treatment intended to make the quarters the spirit has taken up too hot to hold him. Among the Soudanese at the present day may often be seen most fearful scars—the result of treatment for the expulsion of spirits. If a man has pain in a limb, parallel cuts or chops are made in his arm to allow of the exit of the spirit. If the spirit is located in the trunk—causing colic, for instance—the actual cautery is very freely applied to the abdominal wall to drive the evil spirit out per rectum; and so on. In this country scourgings were frequently performed with the same object, but fire, partly from its theological associations, seems to have been the agent most relied on to expel evil spirits. With reputed "changelings," too, the ordeal by fire seems to have been often resorted to under the idea that if the spirit could be driven away a resubstitution of a healthy body would occur, either at once or after the performance of further incantations or exorcisms. This would appear to have been the belief actuating the Irishman now awaiting trial for causing the death of his wife by roasting her at the fire.

A little more than ten years ago a similar case occurred, also in Ireland, and was reported in the daily press. A woman had a child, apparently paralysed in some way, and the neighbours asserted him to be a changeling and desired

¹ See Kennedy, *Legendary Fiction of Irish Celts*. Macmillan and Co.
² Henry IV., Part I., act 1, scene 1.

to treat the child accordingly. The mother refused, so the neighbours watched their opportunity, entered the house when the mother was away, and roasted the child on a shovel with the usual incantations, causing injuries so severe that they were arrested and put on their trial. With the progress of education all these ideas as to the causation and treatment of disease—plausible and poetical as some of them may be—must die out; and the humaner methods of treatment, founded on scientific observation and experience, will become general, to the great benefit of suffering humanity.

THERE are few annual reports of more interest to the public and the profession than that of the Metropolitan Asylums Board. The Board is not in trouble, like other hospital boards, with the eternal difficulty of making both ends meet. It has had given to it by Parliament the work of supplying hospital accommodation gratuitously to all persons and classes affected with certain infectious diseases, and whenever it thinks that a new hospital is needed, or any new apparatus or laboratory or machinery is required, it has but to dip its hands into the deep pocket of the public and the thing is done. There is no Parliamentary discussion of its budget. All that Parliament has done is to remove the restriction originally attaching to these hospitals as places for paupers and to open them to all comers. The Board seems to appreciate the *carte blanche*. The consequence is that the expenditure in connexion with the hospitals has gone up from £350,000 in 1889 to nearly £600,000 in each of the last two years. There is, of course, much to show for such a huge expenditure. There are nine large fever hospitals, two small-pox establishments, four ambulance stations, three wharves, four ambulance steamers, four imbecile asylums, and a training ship for 600 boys. During the past year the actual work of the hospitals has been less than in the previous busy years. Scarlet fever has fallen almost to a minimum, though it shows, we believe, signs of the normal seasonal rise at the present time. The diphtheritic cases are subject to much less variation. The whole number of cases in 1894 was 34,203, as against 57,093—a difference of 12,890.

What is very striking in the report of the Board, and of much significance to the medical profession, is the growing proportion of admissions to notifications. All the notifications of disease are now passed on to the Metropolitan Asylums Board, and so it is enabled to compare the number of cases notified with the number received into hospital. In 1890 the admissions of scarlet fever cases were 42 per cent. of the notifications; in 1892 they had grown to 48 per cent.; and in 1894 no less than 63 per cent. of all the notified cases of this disease were sent into hospital, leaving only 37 per cent. to be treated at home. We shall not be far wrong in estimating that nearly half of all the serious notifiable diseases are now treated gratuitously in the hospitals of the Board. Well may the expenditure of the hospitals advance by leaps and bounds when so large a proportion of the public consents to accept gratuitous medical service and accommodation, apparently with the entire indifference of Parliament. The excuse for such a huge

extension of the system of gratuitous hospital and medical service is what is called the protection of the metropolis from infectious disease, on which the Board congratulates itself. This may be so. We are in no position as yet to compare the amount of infectious disease in the metropolis as a whole under the system of the Metropolitan Asylums Board with what it was before, for the system of notification has only lately been introduced. But certainly we have still much need of protection. There were in 1894 40,925 notifications of disease under the Act of 1889, as against 67,485 in the previous year, 45,892 in 1892, 26,522 in 1891, and 29,795 in 1890. The allusion of Sir EDWIN GALSWORTHY to the question of antitoxin is in good taste and judgment. He treats the efficacy of the remedy as a point still *sub judice*. He mentions that in November the Board accepted the offer of the Royal Colleges of Physicians and Surgeons to supply it with antitoxin. This supply is one on which they can entirely rely, both as to quality and quantity. It is with such antitoxin that cases are now being treated, at the discretion, of course, of the medical officers, and in spite of the absurd protest of the faddists, who would deny to the dying children of these institutions the benefit of such treatment. In a few months we shall have materials for valuable conclusions on the subject. Meantime, though we have little reason to think that the hopes raised by this method will be disappointed, the dignified attitude for all concerned is one of careful observation and reserve. The Board is also indebted to the two Colleges for the bacteriological examination of the exudations in diphtheritic cases. It had come to recognise the need for such examination by the large number of cases certified and sent as diphtheria which turned out not to be so. This difficulty of diagnosis is mainly to be met by bacteriological examination, for many cases without the specific bacillus have all the apparent characters of diphtheria, and *vice versa*. So urgent is this necessity that the Board contemplates the establishment of a bacteriological establishment of its own at an early date. In connexion with this matter, however, we may direct the attention of our readers to a letter which we publish this week from Dr. THURSFIELD, county health officer of Shropshire, in which he expresses a word of warning "as to the risk of accepting the absence of specific bacilli (even after expert bacteriological examination) as conclusive evidence that a suspicious case of throat affection is not diphtheria."

The comparative leisure of the Board during the last twelve-month as compared with the previous year has been spent in anticipating other times of strain and pressure. The managers have in contemplation the erection of two more fever hospitals, three additional ambulance stations, and an infirmary for imbeciles. Such provisions, even at the public expense, we need not say, imply a great amount of anxious and important work, which in the year involved no less than 526 meetings of the Standing Committees of the Board. We must defer any criticism of the medical work and aspects of these hospitals till we have before us the reports of the respective medical officers, which are always full of valuable material carefully and candidly supplied.

Annotations.

"Ne quid nimis."

THE CHITRAL EXPEDITION.

THE Government of India is certainly to be congratulated on its military servants and on the quality of the services they have rendered, as well as upon the successful issue of an expedition which has been followed from start to finish with keen interest in this country and India. And it was only natural that this should be so, for the incidents have succeeded one another with dramatic force and were well calculated to rouse our admiration and enthusiasm. The little band starting from Gilgit on the first note of danger to the relief of Chitral, under the leadership of Kelly and Borrodaile, made such a brilliant display of pluck and endurance that it riveted attention and tended for the time to dwarf the importance of the achievements that were elsewhere being accomplished. Turn which way we may, there have been exhibitions of intrepidity and fortitude in connexion with this expedition of which the nation may well feel proud. Battye, in command of his regiment of Guides, was, when he met his death, conducting their retreat before overwhelming numbers with a skill and coolness that excited the interest and admiration of all. As regards the beleaguered garrison of Chitral, so long cut off from all communication with the outer world, their situation was desperate and their defence heroic. The siege lasted forty-five days, the besieged lost more than a third of their strength in killed and wounded, and were subjected to repeated and energetic attacks from the enemy, besides undergoing the hardships incidental to such a position from insufficient and bad food and failure of supplies. Surgeon-Major Robertson, who was the Political Agent and Governor of Chitral at the time, reported that "the discipline, devotion, and fortitude displayed under circumstances which required all those qualities are beyond all praise." Where all behaved so well it is extremely gratifying to be able to give a very prominent place to the gallantry and devotion of members of the medical service. Surgeon-Major Robertson, who was himself badly wounded during the siege, showed throughout it that he was worthy of the occasion by his sustained courage, ability, coolness, and judgment; and with regard to another medical officer, Surgeon-Captain Whitchurch, the special correspondent of the *Times*, telegraphing from the camp, Dir, says that in the reconnaissance from Chitral Fort on March 3rd, when Captain Baird was mortally wounded, Surgeon-Captain Whitchurch showed conspicuous gallantry in carrying Captain Baird in on his back. Captain Baird (says the correspondent) was severely wounded, and was momentarily lost sight of, but Surgeon-Captain Whitchurch appeared carrying him. He was not, however, able to do this without interruption, but had to leave him every few minutes to go off and rush a wall at the point of the bayonet so as to make the way home. In this manner Captain Baird was conveyed to the fort, where he expired next morning, after strongly urging Surgeon-Major Robertson to bring Surgeon-Captain Whitchurch's bravery to the notice of the authorities. It is a matter of pride and satisfaction to us as medical journalists to have so often to record the gallantry and devotion of members of the medical services, and we have no doubt that on this memorable occasion such conspicuously brave and devoted services will receive the recognition they indubitably merit.

STREET NOISES.

THE essence of good government has been defined as "the greatest happiness for the greatest number," and it is surely time to reiterate the question whether something

cannot be done to make life less unendurable for those who work with their heads and are compelled to live in great cities. We believe we are correct in saying that in no foreign town and in few other British towns is such licence given to anyone to earn a living by annoying his fellow creatures as in London. From an early hour in the morning the air is thick with the raucous yells of men and boys selling race-cards and halfpenny news-sheets. Later in the day the torment is aggravated by piano organs, so-called bands and street singers, while at a late hour of the night it is quite common to be disturbed by hordes of ruffians with voices like foghorns roaring out imaginary and highly spiced details of a murder which has never happened or some even more unsavoury subject. The police, it appears, are powerless. News-vendors cannot be interfered with if they move on, and they do move on—in a circle. Organs, we fancy, can only be moved from in front of the complainant's door, and as a piano organ is perfectly audible 200 yards away this remedy is useless. There is only one remedy, and that is to compel anyone who wishes to make a noise in the street for the purpose of getting money to pay a heavy licence for the privilege of so doing. No one would object to the sale of papers if it were not accompanied by howls worthy of an eighteenth century madhouse. Rates and taxes rise with the utmost regularity every year, and it is not too much to ask that something should be done to obviate a nuisance which gets yearly worse and worse. The ringing of church bells, which, except those of St. Paul's, are always out of tune, should on no account be allowed in London except for five minutes or so before service. Everyone who goes to church knows perfectly well at what time to go, and those who do not go probably do not want to know. In the ages of faith the ringing of bells drove away devils, but the latter-day fiend who yells "Paiper" and grinds organs is proof against their power, and to ring bells is but to add one more unnecessary noise to the large number of necessary ones which already exist. We have pointed out on several occasions that there is no legal right to ring or toll a bell except before morning and evening prayer or on the occasion of a funeral, and that the ringing of a bell previously to the celebration of the Holy Communion, which often now occurs in the early hours of the morning, is wholly illegal and unwarrantable. It is a great torture to many sick and weakly people.

THE WORK OF THE KENSINGTON FEMALE SANITARY INSPECTORS.

THE services of the female sanitary inspector are not, up to the present time, so frequently requisitioned by sanitary authorities that any apology is needed for briefly drawing attention to the work done by the inspectors belonging to the parish of Kensington, more especially as Dr. Dudfield's last monthly report contains an excellent joint account, by Miss R. Squire and Miss A. Duncan, of the work done by them during the year ending March 30th, 1895. The inspectors report that the registered workshops in the parish of Kensington amount now to 567, as against 448 last year, and all these numerous establishments have, they tell us, been systematically visited. In regard to the warming of the workshops, the inspectors report that during the late prolonged frost, when the mean temperature of the air was for some weeks about 28° F., many of the workshops were found to be without proper means of warming. It appears that efforts were made in many instances to obtain a comfortable degree of warmth by lighting the gas-burners at an early hour in the morning and allowing them to burn until work ceased at night. It is pointed out that this improper use of the lighting provision was accompanied by a closing of all means of ventilation, and that thus "the products of respiration added to those of combustion mingled in the stagnant air for a considerable

number of hours." It is to be regretted, the inspectors observe, that although ventilating gas-burners are in the market they do not find a place in the workshops. Attention has also been paid to the subject of gas iron-heaters, and in many instances the inspectors have been able to get these heaters placed in more desirable situations, and even in some cases removed from the workrooms altogether; and they note with pleasure that in Section 19 of the Factory and Workshops Bill, recently introduced by the Home Secretary, "gas-irons emitting any noxious fumes shall not be used." At the same time they express their regret that the clause has been restricted to steam laundries. In the matter of ventilation they do not write encouragingly, the enforcement of proper ventilation meeting, we are told, with the greatest opposition. As they aptly put it, "provision for maintaining the purity of the air of the room unhappily conflicts with the prejudices of the class whose benefit is chiefly sought thereby." The difficulties are, the inspectors observe, enhanced by the fact that the Public Health (London) Act, 1891, confers no adequate powers for dealing with the subject, and they suggest the insertion in the Factory and Workshops Bill already referred to of a clause requiring workrooms to be at all times efficiently ventilated, with special provision for ventilation during meal-times. Ventilation, the report states, is especially unsatisfactory where the rooms are lighted by skylights, in which the openings, often too small, tend to cause a draught of fresh cold air upon the heads of the occupants. Overcrowding seems to have been to some extent successfully dealt with by the service of "recurring" notices, but the inspectors hail with pleasure the fact that the Factory and Workshops Bill proposes to give a legal definition of "overcrowding." Separate sanitary conveniences for the two sexes have in numerous instances not been found by the inspectors, but the action taken has in all cases resulted in the necessary provisions. In dealing with the improvements effected in the laundries of North Kensington they remark: "Many expressions of appreciation have been received from the women themselves, and it is beyond question that the liability at any time to a 'surprise visit' from the inspector, usually spoken of as the 'sanitary lady,' has produced a good effect." We can well believe this, and we congratulate the "sanitary ladies" on their year's work. A perusal of their report side by side with the Factory and Workshops Bill cannot fail to be both interesting and instructive.

THE SUBSTITUTION OF POTATO OR BEET-ROOT SPIRIT FOR GENUINE BRANDY.

THE British Consul at La Rochelle, Mr. Warburton, in his reports from time to time to the Foreign Secretary has frequently drawn attention to the fact of the falsification of brandy in his district, and his recent remarks upon the practices of English dealers, which to some extent exonerate the French merchants from blame, we regard as serious and important enough to call for some authoritative action. Our point of view is solely, of course, the medical one. Brandy is extensively used in medical practice, in which, as every practitioner knows, it is a powerful agent for good; indeed, its timely administration has without doubt again and again been the means of saving life. It is a consideration of these facts which leads us to appeal to the trade, or the authorities who have some sway over the trade, to redeem French "brandy" from the grave charges made concerning its manufacture. Thus, it is stated on the authority of the British Consul that English dealers request French merchants to sell them an article under the name of cognac at a price so low that it is utterly impossible to supply them with anything but potato or beet-root spirit for the money. It takes eight gallons of wine to make

one of brandy, and the first cost of this gallon is about 8s. It is not fit to use until it has been kept for some years, so that there is the expense of storing, loss, &c. to be borne, with the result that a gallon of pure brandy old enough to drink cannot be purchased for less than 12s. In spite of this the British merchants ask the French merchants to supply "cognac" at from 2s. 6d. to 4s., and the offer of such a price amounts to giving the latter their choice between making up this liquor or losing their custom, and many respectable French merchants are obliged to do so. They argue, justly enough, that there is no deception on their part, as the buyer knows that what they give him at this price is not cognac, and if he sells it in England as such they are not responsible. There is plenty of cognac, further writes Mr. Warburton, to be got in this district old enough for consumption at from 15s. per gallon upwards, according to age and quality, by applying to respectable French merchants, and they are only too glad to supply it, as they deplore the injury done to the reputation of the old brandies of this district by the sale of the unwholesome mixtures which have replaced them of late years. It seems to us that this policy on the part of English merchants is simply suicidal, since a knowledge of these facts is surely calculated to lead consumers and the medical profession to obtain their brandy from a source where a guarantee is furnished that it is made from nothing but wine or fermented grapes. Some of our own colonies, for instance, are turning their attention to brandy-growing, and in view of the above statement they deserve every encouragement on this as well as other grounds.

PULMONARY ANTHRACOSIS.

IN a communication to the International Medical Congress at Rome Dr. Tripler of Lyons combated the idea that anthracosis of the lung is in any sense a specific disease peculiar to miners, and advances arguments to prove that this condition is simply pulmonary tuberculosis modified by the special circumstances of the case. His view is as follows: "The phthisis of miners is simply of a tuberculous nature, but predominantly fibrous, in which the carbonaceous infiltration of the pulmonary tissue, especially as regards pathological products, may be so abundant as to cause the lungs to assume such a peculiar aspect as sometimes to render difficult of recognition the tuberculous lesions thus more or less concealed by the accumulation of the carbon." He believes that when animals are made experimentally to breathe air full of particles of carbon the lungs are simply found surcharged with these particles, but without the inflammatory lesions and sclerosis characteristic of pulmonary anthracosis, and that when miners succumb to accidents their lungs are found in a similar state, but without evidence of tubercle. In spite of these facts which Dr. Tripler regards as well known, he states that there is a tendency to describe pneumokoniosis (pulmonary anthracosis) as an independent malady produced by the inhalation of particles of coal, silica, or oxide of iron. The object of his communication was to bring forward some pathological evidence in support of his own view. In one of his cases the patient had succumbed to "la phthisie charbonneuse," and on post-mortem examination the lungs were found to be full of particles of carbon, and much sclerosed, but further examination demonstrated the existence of a cavity at one apex and the presence of caseated tubercle. It is possible, of course, to argue that the tubercle was a secondary result of the infiltration of the lungs with particles of carbon. Dr. Tripler combats this view. In the case in point the patient had worked for fifteen years in mines without developing any pulmonary lesion, and had ceased from this occupation for six years before showing signs of commencing disease of the lungs. In a second case brought

forward by Dr. Tripler the patient had breathed a carbonaceous atmosphere for thirty-one years without any pulmonary trouble, and finally succumbed to cancer of the stomach. On post-mortem examination the lungs were found to contain particles of carbon widely disseminated, and specially numerous in the lymphatics, but without any sign of tubercle. The writer further argued that the amount of carbonaceous infiltration of the lungs bears no relation to the probability of finding tubercle. The latter may be found in miners with little or much carbon in their lungs, and in those who have spent few or many years in occupations involving the constant respiration of carbonaceous particles. Cases such as those brought forward by Dr. Tripler are, of course, inconclusive, but they must be allowed reasonable weight. They certainly tend to corroborate the view that pneumokoniocis or pulmonary anthracosis is not an independent affection with a definite cause and definite natural history, but simply one of the many varieties of pulmonary phthisis.

"INQUEST AT STAPLETON: A QUESTION FOR THE MEDICAL COUNCIL."

SUCH is the heading of a report in the *Bristol Mercury* of an inquest at Stapleton held by Mr. E. M. Grace concerning the death of Walter John Edward Hinton, aged thirty, a coachsmith. The evidence went to show that the deceased had no local medical attendant, but was taking a certain balsam for which the ordinary charge was 22s. and 11s. 6d. per bottle. Dr. J. Ambrose said he had made a necropsy and found death to have been caused by syncope, though deceased was suffering from advanced phthisis. Life might have been prolonged had he had medical attendance weeks ago, but there was no chance of saving it in the advanced state of lung disease. A letter was read from "Dr. Congreve" of Coombe Lodge, Peckham, London, S.E., to a relative of the deceased, commending the balsam and prescribing for diarrhoea, though suggesting his continuing under the care of a local medical man, observing that the balsam would not interfere with the medicine the local practitioner might order. The coroner intimated that it was his duty and intention to send the letter to the General Medical Council.

DISEASED MEAT AT BLACKPOOL.

A GOOD illustration was afforded recently at Blackpool of the enormous difficulties which may be experienced in bringing a prosecution for the exposure of diseased meat to a successful issue in a court of law. In the case in question a butcher was charged by the Blackpool sanitary authority under Sections 116 and 117 of the Public Health Act (1875) with having exposed for sale certain meat alleged to have been unfit for human consumption. The inspector of nuisances—an officer of fourteen years' experience—seized seventeen pieces of meat exposed for sale in the defendant's shop, and after ample opportunity had been afforded to, and taken advantage of by, the defendant's witnesses to inspect the meat seized it was seen by a magistrate and condemned. The inspector gave evidence as to the condition of the meat, and Dr. Jasper Anderson, the medical officer of health, stated that the changes in the state of the meat were such that it would be dangerous for human consumption. Dr. Anderson was of opinion that the beast from which the meat was taken had been suffering from a chronic wasting disease, but on account of the viscera being absent he was unable to state to what this condition was due. This witness's evidence was practically corroborated by Dr. Leonard Molloy and several other witnesses, among whom were veterinary surgeons and butchers. For the defence a large amount of evidence was brought forward, the witnesses also including medical men, veterinary surgeons, and butchers. As rebutting evidence the prosecution called the county

medical officer of health and Professor Delépine, Professor of Pathology at Owens College, Manchester, both of whom declared that the meat as described by the prosecutor's witnesses would be quite unfit for human consumption. Considerable stress was laid by the defence upon the fact that the viscera of the beast from which the meat was taken had not been examined; but it would surely be unreasonable to make the condemnation of diseased meat exposed for sale in a butcher's shop dependent upon the examination of the viscera. The bench fined the defendant £5 and costs, or two months' imprisonment; but probably, in spite of this, the prosecution must have been a somewhat heavy expense to the Blackpool sanitary authority, as the costs awarded by the bench only amounted to £13 15s. 6d. It is, however, only fair to state that in answer to the defendant's solicitor the bench stated that there was no evidence that the butcher was aware of the meat being unsound. Dr. Anderson is certainly to be congratulated on having been successful in what was obviously a very difficult case, and the evidence shows what very costly proceedings prosecutions of this kind may sometimes become.

A MEDICAL PALÆONTOLOGIST.

IN the Palæontographical Society's volume for 1894, which has just appeared, Dr. Wheelton Hind of Stoke-on-Trent contributes the commencement of a monograph on the Carbonicola, Anthracomys, and Naladites of the Coal Measures. We congratulate Dr. Hind on the energy he has displayed in the production of this work, and we are proud to recognise that the scientific spirit of our profession is sometimes shown in the extension of knowledge not always directly related to medical subjects. The monograph has much valuable information in the introduction and in a chapter headed "Critical Bibliography." The rest of it is naturally almost entirely descriptive. It is accompanied (as are all the monographs published by the Palæontographical Society) by a series of very beautiful plates. A very large number of these drawings are from specimens in Dr. Hind's own collection. For the information of the reader unlearned in geology it may be stated that Carbonicola, with which this volume principally deals, is a genus of bivalve molluscs, probably of freshwater origin, and most closely allied to *Unio* and *Anodon* amongst living genera.

TRAUMATIC GLYCOSURIA.

"EVER since the time of Claude Bernard, who first experimentally demonstrated the existence of the so-called sugar centre in the floor of the fourth ventricle, head injuries have been recognised as playing a certain part in the etiology of some cases of diabetes." Such is the introduction to a paper by Dr. F. A. Higgins and Dr. J. B. Ogden in the *Boston Medical and Surgical Journal* of Feb. 28th. The paper is the result of observations made in 212 cases of head injuries. The writers remark that in addition to permanent glycosuria following traumatism of the head there is another form mentioned by some observers, and of which a number of cases have been reported. This last form is merely transitory, and comes on directly after the traumatism or in a few days. On the other hand, the permanent form of glycosuria occurs at a period of weeks or even months afterwards. After giving an account of the various classes of cases met with they summarise their conclusions as follows: 1. That, after injury, sugar may appear in the urine as early as six hours and disappear within twenty-four, the average time for its appearance, however, being from eight to twelve hours; and for the disappearance of the same from the fifth to the ninth day. 2. That a small proportion of the cases may exhibit a permanent glycosuria from the date of injury to the head. 3. That acetone and diacetic acid are rarely, if ever, found in such cases, excepting where the condition becomes a permanent

glycosuria, and even then probably only after a number of months or years. 4. That, of the twenty sugar cases recorded in the paper, eleven (55 per cent.) had received an injury to the right side of the head, five (25 per cent.) to the left side, three (15 per cent.) to the occiput, and two (10 per cent.) where there was no external evidences of violence. 5. That it is impossible in the present state of the knowledge of the pathology of diabetes and glycosuria to draw any inferences from the necropsies which have been obtained. They are, however, reported in full. 6. There is little to be said in regard to the mortality. Of the twenty cases eight died, six being the direct result of severe injuries, one from intercurrent disease, and one from the probable effects of alcoholism. In the 212 cases sixteen were fatal, 50 per cent. of these having glycosuria. Albumen, together with casts and abnormal blood, was found in every case containing sugar, probably secondary in most instances to the renal irritation produced by the sugar, even though it had been eliminated only a short time.

FEES FOR NOTIFICATION OF DISEASE.

AT the Keighley County Court held on April 24th his honour, Judge Gates, Q.C., said that after further consideration he was satisfied that he was right in deciding at the previous court against the plaintiff in an action brought by Mr. Beckett, L.R.C.P., of Cullingworth against the Bingley Outer District Council to recover a fee for the notification of a case of infectious disease which happened to have been previously notified by another medical man. Leave to appeal was refused. We have not the details of this case before us, but on the general question which is here involved we would recall attention to the letter of the Local Government Board to the Uppingham rural sanitary authority, which was published in our fourth article on Difficulties under the Infectious Disease (Notification) Act,¹ and in which that Board hold distinctly that where two practitioners are called in to visit one and the same patient, either at the same time or successively, "both are, in strict law, required to send certificates of notification, and these must be duly paid for by the sanitary authority." The Local Government Board are not in the habit of giving opinions of this sort except on skilled legal advice, and if the Keighley case referred to comes within the scope of the Board's letter it is one that ought not to be allowed to drop.

IRRIGATION AND CLIMATE.

MR. W. E. GARSTIN, head of the Public Works Department in Egypt, writes as follows in an appendix to Lord Cromer's annual report on that country:—"An unusually large area of land was planted with cotton in 1894. Unfortunately, the cotton worm during the summer and the cold and fogs during the autumn months caused between them such damage to the plants that the yield is estimated to be from 10 to 15 per cent. less than that of 1893." Referring to this statement, a correspondent, who lived for several years in Egypt, would be glad to know whether there is any truth in an assertion, which he has heard made by many people, natives as well as foreigners, that of recent years the climate of the Delta has become much damper than it used to be, and that augmented irrigation, including the holding up of water by *barrages*, is responsible for the change. As far as we are aware the only meteorological records in Egypt that extend back for a considerable number of years refer exclusively to Alexandria, where the climate is quite different from that prevailing inland. The note upon the Public Works Department in the appendix to Lord Cromer's report, referred to, also gives a good deal of information about irrigation,

the *barrage*, drainage, reservoir projects, and crops. What seems to be much required at the present time in connexion with the public works in Egypt is a system of drainage and pumping. Irrigation without drainage gives rise to water-logging of the soil. Every drop of water turned on to the soil should be passed through it and carried away by an effective drainage system, with the exception of that necessarily evaporated by the sun's rays. It is, therefore, probable that there is some measure of truth in the belief that the atmospheric moisture and the prevalence of fogs have somewhat increased, but we are not aware that any changes in this respect have ever been scientifically observed and recorded. As far as we are competent to judge, we should say that the difference between modern and ancient methods of irrigation in Egypt could not produce any marked alteration of climate. The volume of water delivered by the Nile does not vary much from year to year, and the temporary detention of a small portion of it is all that can be laid to the charge of extra irrigation. But some of our readers may, perhaps, be able to supply information on the subject.

IMPORTED FROZEN MILK.

THE rapidly increasing importation of frozen milk from Holland, Sweden, and other places is a serious question, since so far as we can gather there is no guarantee of its being derived from an uncontaminated source. Our own centres of milk production are, of course, placed under strict sanitary regulations, so that as far as possible disease may not be disseminated by the means of so ready a carrier as milk has been proved to be. The efforts, therefore, of our sanitary authorities to prevent milk-borne diseases may, for aught we know, be seriously handicapped. We trust that the Government will make some inquiries into this important and, it may be, very serious matter. The position is absurd and is also alarming if it can be shown that while the strictest preventive measures are taken against the importation of diseased cattle no steps whatever are provided against the importation of milk the consumption of which may possibly be fraught with equally serious issues. The question, too, has an important bearing upon the subjects dealt with by the Royal Commission on Tuberculosis, whose report we considered last week.

CHLOROFORMISATION BY MINIMAL DOSES.

IT is a curious revelation of the uncertainty which exists in the minds of the profession with regard to chloroform that we find such conflicting plans suggested to ensure safety; on the one hand we are told it is almost impossible to kill, while on the other it is averred that to use chloroform at all is little short of committing manslaughter, while the surgeon who desires it is accused of "inciting to kill." Happily such fantastic extremes are seldom found in this country, but when we come to questions of how to give the anæsthetic views as diverse are found to obtain. Simpson's oft-repeated formula, "The chloroform vapour must always be exhibited as rapidly and in as full strength as possible," and Syme's even more trenchant rule, "Do not stint the quantity of chloroform," and the more recently expressed views of the Hyderabad Commission seek salvation in large doses freely given, while others tell us that the only safe way of using the drug is a guttatim method. Thus Mr. Martin Coates, writing in our columns in 1882,¹ stated that he employed chloroform in doses of a few minims at a time, using Snow's inhaler, and believed his results, twenty-four years of active surgical practice without a death, were due to his method. Since then many have adopted minimal doses of chloroform and have been immensely impressed by their success. Messrs.

¹ THE LANCET, Feb. 16th, 1895.

¹ THE LANCET, Dec. 23rd, 1882.

Krohne and Sesemann's apparatus, which we figured and described in our columns,² appears to offer the best method of obtaining a free dilution of chloroform vapour and of reducing to minima the actual quantities used. It would be obviously impossible for us to pronounce that the one safe road to chloroform anaesthesia is through the gate of minimal doses. The remarkable statistics of Simpson, of Syme, of Lister, and of Lawrie show what can be done with unmeasured, unstinted dosage, while Snow's, Clover's, and Junker's instruments show how much safety can be ensured by methods which definitely mix the narcotic with air and permit of the inhalation of a low percentage vapour.

KINGSLERE DISTRICT COUNCIL AND MEDICAL REMUNERATION.

THE *Reading Mercury* of April 27th reports that at a meeting of the district council for Kingsclere "Dr. Maples was awarded £1 per annum for extra duties on account of the parish of Newtown having been transferred from Newbury Union." It would be curious to know what are the details of the extra duty that is to be so handsomely rewarded by the district council. We may anticipate a rush to Newtown as a parish so healthy as to need only so much attention from an officer of health as will be remunerated by less than sixpence a week.

PARALYSIS FOLLOWING NON-DIPHTHERITIC MEMBRANOUS CROUP.

REFERENCE to a case of this character, described in the *Archives de Médecine Expérimentale et d'Anatomie Pathologique* by Dr. Bourges, is made in a recent number of the *Neurologisches Centralblatt*. A boy aged seven developed, after an attack of pseudo-membranous sore-throat, paralytic symptoms affecting the palate, the ocular muscles, and the lower extremities. The mother of the child passed through a similar illness, but without the paralytic sequelæ. Bacteriological investigation of both cases failed to reveal the presence of Löffler's bacillus, but demonstrated the presence of other cocci and bacilli. But, as the writer in the *Centralblatt* points out, the case is a by no means conclusive one, for the membrane in the boy had been treated with a solution of corrosive sublimate on two occasions before the examination was made, and it is possible that this treatment may have been the means of getting rid of the bacilli.

CARDINAL VAUGHAN ON FREE RECREATION.

A PROPOSAL made by Cardinal Vaughan at the late meeting of the Sanitary Conference at Manchester (a report of which will be found in our Manchester correspondent's letter) is of interest as illustrating the progress amongst us of a benevolent socialism. The suggestion aims at the establishment of winter recreation halls in the poorest districts of large cities. In these halls musical and other entertainments will be given and suitable refreshments provided, the latter at cost price. The responsible promoters will be the civil authorities. The scheme thus briefly sketched is not without merit, either in its plan or its intention. There is a tendency in modern legislation, as Cardinal Vaughan observes, towards the recognition of health, comfort, and moral welfare as objects within the scope of its operation. The project above mentioned, moreover, is not in itself novel. It has already found a thousand means of expression in limited and local voluntary agencies, commonly more or less religious in character, but not necessarily so. Extended to the scale proposed by Cardinal Vaughan, however, it draws even more largely upon public charity, and it raises the question whether self-help or municipal assistance furnishes the best means of attaining the end in view. We

believe that the former is still as a rule effectual for its purpose, and that it can be supplemented if required by voluntary aid, and if this be the case any large appropriation of public funds to purposes of recreation seems hardly to be called for. The effect of the civic recreation hall as a competitor with other like voluntary institutions, must also be reckoned with. It has been stated that the proposed scheme is calculated to foster domestic life by providing for the family a common focus of amusement. To a limited degree, no doubt, this is true. At the same time we must remember that order, thrift, industry, and all else that goes to constitute the backbone of family life come less by pleasure-seeking (especially out of doors) than by more deliberate processes of education.

THE PLAGUE AT MACAO.

It seems that several deaths are alleged to have taken place at the Portuguese settlement of Macao from plague, and that the disease is stated to have been prevailing there for about a fortnight. Communication between Macao and Hongkong is quite unrestricted, and this has given rise to a good deal of anxiety at the latter place, where the people are desirous of having a rigid quarantine enforced against the infected settlement. His Excellency the Governor of Hongkong is opposed, however, to any action being taken in this direction, and this has led to the resignation of the unofficial members of the sanitary board. Without further particulars as to the exact nature and extent of the disease prevailing at Macao it is difficult to pronounce any definite opinion on the matter. If the disease be veritably and indeed plague it is indubitably contagious, and if any doubt exists as to the exact nature of the malady all persons coming from Macao should at least be medically inspected, and segregated if necessary. We strongly suspect that local insanitary conditions have a good deal to do with the existence of this and other diseases in China, and that in any case the removal of these should occupy the attention of the people at Hongkong. It can scarcely be, we think, that the Governor and official members of the sanitary board would incur the responsibility of opposing the wishes of the colony in regard to the establishment of quarantine unless they had some grounds for doing so of which we are ignorant at present.

THE STOMACH TEST IN MURDER TRIALS.

In the *Boston Medical and Surgical Journal* of Feb. 28th Dr. Gustav Liebmann contributes a short paper on this subject. He states that the object of this test is to ascertain, by the presence or absence of solid contents or by the intermediary stages of liquefaction of food found in the stomach, how far the process of digestion has advanced, giving thus a clue as to the time at which the death of the victim has taken place, provided the time of the last meal be known. In order to arrive at an exact, or at least approximately exact, conclusion, the first and imperative condition would be a uniformly established schedule of time in which the different phases of digestion should be completed. If there be such a physiological law, from which there is practically no deviation, we should place full reliance upon the test; but if there be, in healthy people even, numerous exceptions or deviations the test must of necessity be open to errors. Dr. Liebmann considers that this latter proposition is the true one. The different variations in the duration of the digestive process depend upon the following conditions: 1. The length of time necessary for the transformation of solids into chyme in healthy individuals varies a great deal according to the digestibility of the different foods. 2. The length of time necessary to expel the ingesta from the stomach into the duodenum in the healthy individual varies according

² THE LANCET, Nov. 3rd, 1894.

to the quantities of food taken. Not only does it take a longer time for larger quantities to be impelled on, but the motor activity of the stomach walls is diminished by the greater distension produced by the larger amount of food present. Thus, pieces of meat are frequently found a day or longer after ingestion. 3. The shorter or longer stay of food depends on the amount of acidity, which varies in different stomachs even within the border lines of health. 4. Much variation even in health is caused by individuality, by presence or absence of pepsin, hydrochloric acid, psychical factors, and emotions (fright, fear, grief, or the opposite, as joy or exaltation). We see, therefore, that owing to the many physiological variations, which do not permit of any reliable deductions even in the healthy, the forensic value of this test must be considerably impaired.

DIRECT LARYNGOSCOPY.

Dr. KIRSTEIN of Professor Senator's polyclinic in Berlin has devised¹ a new method of examining the larynx and trachea, in which the interior of these organs is seen directly and not by the intervention of a mirror or prism. He does not say, however, that his plan is applicable generally, but only that in "many persons" it can be carried out. The patient is placed on his back in the horizontal position with the head hanging down, and an œsophagoscope is introduced. A metal speculum in the form of a tube about ten inches in length can then be passed behind the epiglottis and illuminated by a "Caspar's electroscope" and through it the larynx viewed with the naked eye. It does not do for the observer to wear spectacles, as these rapidly become dimmed with moisture. The tube itself acts as a tongue depressor, being a lever whose fulcrum is the edge of the upper incisors. Dr. Kirstein does not, of course, suggest that this method should ordinarily be employed instead of the common method of laryngoscopy, but he thinks that in some cases it will be found capable of extending usefully our methods of laryngeal and tracheal examination, and he asserts that it is by no means so severe a procedure as may be imagined, and that, especially if cocaine is employed, it causes the patient no distress either at the time or subsequently.

THE AFTER-CARE ASSOCIATION.

THE annual report of the council of the After-care Association for Poor Persons discharged recovered from Asylums for the Insane has just been issued for the year 1894. Attention is drawn to the fact that this association is the only one in this country that offers the special help afforded by it to those poor people who are recovering from insanity. That such people are very often in great need of help when discharged from asylums is well known to medical men, especially those engaged in the treatment of insanity. The general public, though ready enough to think that people are often sent to asylums unnecessarily, is very unwilling to offer employment to those who have recovered from an attack of mental disorder; and the popular belief that a man or woman who has been ill thus may "break out at any moment" and is quite unfit to be trusted in any way is a strongly fixed one. Hence the special need of such an association, which is really entitled to all the help the benevolent can bestow upon it. The number of cases assisted in 1894 was 118, as compared with 81 in 1893, 100 being men and 18 women. Cases have been assisted by being placed in the association's convalescent home, by boarding them in country cottages, by grants of money or clothing, by finding them occupation, and in other ways. It is satisfactory to notice that the receipts from subscriptions and donations show

a fairly large increase for the year. Local district secretaries have been appointed in many districts, and more lady guardians have become members of the society. Instances are given of cases helped during the year. The council invites the warm coöperation of the medical superintendents of the various asylums and guardians of the poor throughout the country. Since the issue of the report the association has, unfortunately, lost the services of its chairman, the late Dr. Hack Tuke, whose interest in this work was well known, and who was also one of its trustees. The secretary is Mr. H. Thornhill Roxby, Church House, Dean's-yard, S.W.

SAMPLES FOR REFERENCE UNDER THE FOOD-AND DRUGS ACT.

WE have frequently commented upon the loopholes of escape which the Food and Drugs Act affords to the seller when those entrusted with the administration of the Act fail to observe, it may be, some slight point when purchasing the sample. In a case reported last week, however, a positive blunder was committed, inasmuch as the bottle containing the sample reserved for analysis at Somerset House was only half full, the seal was not perfect, the cork had been pierced, and the sample measured only three ounces. An analysis by the referees was, of course, impossible, not only on account of the smallness of the sample, but also because the milk, having been exposed to access of air, had undergone certain changes which preclude a satisfactory analysis. As the magistrate (Mr. Bushby) remarked, this was a serious reflection upon the prosecution, as the sample in question had been retained in the custody of the sanitary inspector of the parish, and the case had broken down. The summons was dismissed. In regard to milk especially, or other perishable articles, it would be satisfactory if the Government could see their way to establishing a laboratory especially equipped for the immediate analysis of all duplicates taken under the requirements of the Act, whether their genuineness is suspected or not. This step, it seems to us, cannot be utterly impracticable, but of course it would involve a good deal more work than is done at Somerset House at present; milk, however, is one of the most important members of our food-supply, if indeed it is not the principal article about the quality and purity of which there should be no question.

THE HEALTH OF PROFESSOR HUXLEY.

WE are glad to be able to state authoritatively that the Right Hon. T. H. Huxley has lost no ground during the last few days. His temperature is only very slightly raised, and though he is still troubled by cough and expectoration, he is able to take a fair amount of liquid nourishment, and sleeps well. His general condition remains weak.

WE regret to announce the death of Professor Carl Ludwig, the eminent physiologist, which occurred in Leipzig on April 26th. A short account of his life and work from the pen of our Berlin correspondent will be found in another column. We hope to publish a full obituary notice next week.

A TELEGRAM from Buenos Ayres says that advices received there from Santos announce that yellow fever in its severest form has broken out at Santos, the daily mortality being six.

WE are asked to state that the Clinical Museum, Great Portland-street, is open every Tuesday at 2 P.M., and that there is a demonstration at 4 P.M.

THE subscription list to the Sir Andrew Clark Memorial Fund will shortly be closed.

¹ See a preliminary communication in the Allgemeine Medicinische Central-Zeitung, April 24th, 1895.

REPORT OF THE COMMITTEE ON PRISONS.

I.

In June last year the Home Secretary appointed a departmental committee under the chairmanship of Mr. Herbert Gladstone, M.P., to inquire into a variety of circumstances and considerations having relation to the administration of local and convict prisons and to the treatment of the prisoners confined therein. In their report the committee say that they "could not but be cognisant of the circumstances under which the inquiry was instituted. In magazines and in the newspapers a sweeping indictment had been laid against the whole of the prison administration. In brief, not only were the principles of prison treatment, as prescribed by the Prison Acts, criticised, but the prison authority itself and the constitution of that authority were held to be responsible for many grave evils which were alleged to exist." The committee, therefore, very properly applied themselves to the task not only of examining into present conditions of prison administration, but of endeavouring by inquiry to discover whether any and what better system and methods of treatment could be adopted.

The groundwork of the treatment of convicted prisoners in local prisons is laid down by the Act of 1865, and further provisions, including certain modifications, were introduced by the Act of 1877. Since 1865 the main principles of prison treatment have not been altered, except in detail, and in so far as they may have been affected by the radical change in the administration effected by the Act of 1877. Indeed, it may be said generally that neither those principles nor the administrative system laid down by the Acts of 1865 and 1877 had been brought into question until the present inquiry was instituted. Convict prisons—i.e., prisons for the detention of prisoners sentenced to penal servitude—have been dealt with separately by the Penal Servitude Acts, 1853, 1857, 1864, the Prevention of Crimes Act, 1871, and certain other subsidiary Acts. During the last forty years important alterations have been made in the treatment of prisoners, but continuity in the administration by the directors has been maintained throughout. With these preliminary statements and after acknowledging the great assistance that they have derived from previous inquiries, the committee pass on to a "general review" of the management of English and Welsh prisons, with regard to which they "consider that the long and able administration of Sir E. Du Cane has achieved a large measure of success." At the outset the committee gave a return which shows that while the population has increased the number of convicts and local prisoners has decreased. The number of convicts has diminished from 10,139 in 1877-78 to 4383 in 1893-94; and the local prisoners—i.e., persons sentenced to shorter terms of imprisonment—have decreased in numbers from 20,833 to 13,850 during the same period. The committee say that "the decrease of the prison population cannot be taken as a correct indication of a corresponding decrease in crime." No; it is no more a correct indication of a corresponding decrease of crime than the filling of our churches on Sunday would be a correct indication of a corresponding increase of religion. Churches are built to attract, prisons to deter, and so far as churches and prisons respectively attract and deter, are filled and are not filled, so far may they be regarded as successful in attaining the object for which they were built. For it is obvious that if prisons were made attractive in any degree they would not be fulfilling their functions and their existence would become a stimulus to crime. We would prefer to express the position by stating that the decrease of a prison population cannot be taken as expressing the proportion of influence which the prison system has in bringing about the decrease. Some types of individuals are more impressed and influenced for good by prison life than others.

The general review is summed up in the following terms: "If the condition and treatment of prisoners at the present time are compared with what they were sixty, forty, or even twenty years ago, the responsible authorities can justly claim credit for great and progressive improvement. The bad prisons have disappeared. In the full consciousness of these improvements it was not unreasonable that there should have been a somewhat rigid adherence to the lines of the Prison Acts and great faith induced in the principles which they laid down. Moreover, the various inquiries which have taken

place have all resulted in the general affirmation of the principles which were prescribed by the Acts. This was conspicuously so in the case of the lengthy inquiry into Irish prisons in 1885, when one of the chief efforts of the Commission appears to have been to raise the administration of the Irish prisons to the English level. We do not consider, therefore, that there is reason for general condemnation of a system which resulted originally from careful inquiry and much deliberation, and which was specially and successfully designed to put an end to many glaring and patent evils. Similarly, we do not consider that it is right to lay the burden of all the shortcomings of the prison system on the central prison authorities, who have carried into effect under successive Secretaries of State the Acts approved by Parliament, who have loyally and substantially carried out the various recommendations made from time to time by Commissions and committees, and who, as administrators, have achieved in point of organisation, discipline, order, and economy a striking administrative success. Nevertheless, we feel that the time has come when the main principles and methods adopted by the Prison Acts should be seriously tested by the light of acquired experience and recent scientific research."

The general effect of the passing of the Prison Act of 1877 is next dealt with. By that Act all local prisons were transferred from the local authorities in counties and boroughs to the Government and placed under the authority of a newly constituted Board of Commissioners acting subject to the authority of the Secretary of State. The intention of the Act was to produce an improved and uniform system through the strong and centralised administration of the Government, but at the same time to preserve local influences and the co-operation of the visiting justices by the institution of visiting committees to whom were assigned very extensive responsibilities and powers. In the opinion of the committee the intention of the Act in this respect for the most part has been a failure. The centralisation of authority, they say, has been a complete success in the direction of uniformity, discipline, and economy; but, on the other hand, it carried with it some inevitable disadvantages. "The great, and as we consider the providential danger of this highly centralised system has been and is that, while much attention has been given to organisation, finance, order, health of the prisoners, and prison statistics, the prisoners have been treated too much as a hopeless or worthless element of the community, and the moral as well as the legal responsibility of the prison authorities has been held to cease when they pass outside the prison gates. The satisfactory sanitary conditions, the unbroken orderliness of prison life, economy, and high organisation are held, and justly held, to prove good administration. But the number of recommissions has led us to think that there is ample cause for a searching inquiry into the main features of prison life. From the evidence submitted to us it appears that as a criminal passes into the habitual class, prison life, subject to the sentences now given, loses its terrors as familiarity with it increases." This last sentence is of the nature of a truism, and we can hardly picture in our minds the possibility of any other effect of familiarity with prison life. As regards what we may call the extra-mural requirements indicated by the committee, we would ask whether it has ever been held to be the duty of prison officials, except in so far as they are ordinary citizens, to follow up the discharged prisoner and see what he does or what becomes of him after he has become merged in the general community. The proper treatment of a prisoner is one thing, but the social supervision of an ex-prisoner from philanthropic motives is so voluntary in its character that it is well to detach it as far as possible from the atmosphere of officialism, which is so apt to place the individual in a compromised position, if not actually to damage his prospects. We honestly confess that we have no great faith in the reclamation of "old hands." And why the failure of their reclamation should be tacked on as in any sense due to the centralised system or referable to it we fail to see. The "moral condition" of a habitual criminal when he leaves prison or when he enters it is a veritable *ignis fatuus*; and there are few persons who would undertake to estimate it. Asking the question, Is recidivism increasing? the committee in a tentative way deal with this important subject, and in the end they say that it is difficult to avoid the belief that the proportion of reconvictions during the last twenty years has increased. But the reconvictions take place among the older hands, for it would appear that of every 100 who go to prison a first time seventy do not return, while of those convicted a fifth time as many

79 per cent. do return. This bears out the opinion expressed by the committee that so far as first offences are concerned the present prison treatment in convict and local prisons is amply sufficient for the purposes of deterrence. To our mind the non-return to prison of first offenders is the all-important factor for consideration, and we certainly agree with the committee when they urge that the most determined effort should be made to lay hold of incipient criminals and to prevent them by strong restraint and rational treatment from recruiting the habitual class. The committee point out that the headsprings of recidivism are doubtless in a large measure to be found in the social conditions of the general population. Lads grow up predisposed to crime and eventually fall into it. Mr. Davitt told the committee that he was speaking to an educated habitual criminal in Dartmoor and was pointing out how foolish it was, apart from the immorality of the thing, to risk getting seven years' penal servitude for stolen goods of the value of £10 or £20. The man replied, "Well, yes, that is all right coming from you, but put yourself in my position. I never knew my father or mother; my first recollection is being turned out of a workhouse. I fell among thieves. I got educated in crime. I learned to read and write in prison. Unlike you, I have had no moral training. Now I hold that man is naturally a thief. Take for instance a child in its mother's arms: anything that excites its fancy it wants to get, and if that natural feeling is not corrected by parental training and moral influence and education it gets stronger as the child grows older. Now I am such a product of your civilisation. You allowed me to grow up with these animal instincts uncorrected, and then you send me to prison when I exercise them."

The conclusion arrived at is that the habitual criminals can only be effectually put down in one way, and that is by cutting off the supply (during incipency). The improvement of general social conditions is the work of the community. But the opinion that some of its worst and most dangerous products can be reclaimed by special and skilful prison treatment and that many of these would lead honest lives in different surroundings is emphatically maintained by many of the most capable and experienced witnesses.

THE SURGICAL CONGRESS IN BERLIN.

(FROM OUR BERLIN CORRESPONDENT.)

(Continued from p. 1078.)

SITTING ON APRIL 18TH.—(Continued.)

Congenital Dislocation of the Hip-joint.

PROFESSOR HOFFA (Würzburg) showed some cases of Congenital Dislocation of the Hip-joint which he had treated successfully by operation. He opened the joint after Langenbeck's method and formed an artificial acetabulum in which the head of the femur was inserted.—Professor Lorenz (Vienna) said that it is of great importance in this operation to save the muscles and tendons which are attached to the femur. He accordingly makes the incision in front, carefully avoiding the muscular insertions, and after the opening of the joint at this place an artificial acetabulum is formed and the head of the femur is brought into it by gradual traction.—Professor Mikulicz (Breslau) and Dr. Heusner (Barmen) recommended the treatment by orthopædic apparatus.

Operations on the Pancreas.

Professor Krönlein (Zürich) said that carcinoma of the pancreas was rare, only 6 per cent. of all carcinomata being found in this organ. Growths situated in the small end of the pancreas are the most favourable for operation. He reported a case of sarcoma where the isolation of the pancreas was very difficult and where ligature of the pancreaticoduodenal artery became necessary; gangrene of the colon resulted and caused the death of the patient on the seventh day.

SITTING ON APRIL 19TH.

Resection of the Gasserian Ganglion.

Professor Krause (Altona) has performed this operation several times for trigeminal neuralgia by a method which he has described at former meetings of this Congress. The effect was in all cases very satisfactory. By this operation it was proved that the trigeminal is the gustatory nerve for the apex and the sides of the tongue.—Professor König

(Göttingen) said that he had seen severe hæmorrhage from the middle meningeal artery in the course of the operation.

The Etiology and Histogenesis of Carcinoma.

Professor Tillmanno (Leipzig) accepted the theory of Waldeyer and Ribbertz that carcinoma arises from any sub-epithelial proliferation by which the epithelial cells are isolated and made to grow abnormally. Experiments in support of the alleged zymotic origin of cancers have hitherto been without success, the bacilli found in the growth not being capable of producing real carcinoma in other persons. In patients suffering from carcinoma the growth could sometimes be transferred from one organ to another, but a transfer from one person to another has not yet been proved. Carcinoma often arises from prolonged chemical or mechanical irritation; in particular, the use of tobacco is very dangerous as regards the tongue and lips. Hereditary predisposition is unquestionable. Females and negroes are especially liable to it. Cases of carcinoma are rapidly on the increase, their number being at present four times greater than it was forty years ago.—Dr. Geissler (Berlin) showed a dog to which he had communicated carcinoma by inoculating pieces of a cancer taken from a woman.—Dr. Haussmann (Berlin) believed that the new growth was not carcinoma.—Dr. Friedrich (Leipzig) said that he had made experiments in reference to the therapeutic action of bacteria toxins on malignant growths. In carcinoma no effect at all could be discovered, but he had reason to believe that in sarcoma his researches might be more successful. He hoped to be able to give more particulars at next year's Congress.—Dr. Lassar (Berlin) showed patients with cancers of the skin treated successfully by Fowler's solution.—Professor von Bergmann (Berlin) declared these cases to be not cancers but adenomata of the sebaceous glands. Patients with cancers had very often come to him to be operated on soon after an apparent cure had been effected by Dr. Lassar's method. The growth is then usually much larger, and its removal becomes more difficult than it would have been if the previous arsenical treatment had not been undertaken.—Professor Kocher (Berne) said that the effect of arsenic was only of short duration.—Professor König protested against the publication of methods which have the effect of causing operations to be deferred until too late.

The Diagnosis of Syphilitic Growths.

Professor von Esmarch (Kiel) called the attention of the meeting to Sarcoma-like Syphilitic Growths. Sarcomatoid tumours occurring in patients with other syphilitic symptoms, and very soon reappearing after extirpation, are to be regarded as probably syphilitic. Tumours in the muscles of patients suffering from deferred hereditary syphilis are gummatous in 90 per cent. of the cases. The diagnosis is difficult and only to be inferred from the results of anti-syphilitic treatment.

Tuberculosis of the Knee-joint.

Professor König gave a statistical account of the cases which he had attended in the University Hospital of that town. There were 725 patients suffering from this disease, but he had notes of only 615, of whom 410 (= 65 per cent.) have already died, the great majority (340 cases = 80 per cent. of the total deceased) having succumbed to tuberculosis. Conservative methods were employed for 184 patients; in 150 arthrectomy and in 300 typical resection were performed, and in 91 amputation became necessary. In numerous instances iodoform or carbolic acid was injected into the joint, and in many of these cases operations had to be afterwards performed. He had found, contrary to the experience of other surgeons, that injections of carbolic acid gave a better result than injections of iodoform, the power of moving the joint having been regained by thirteen out of forty patients treated with iodoform, and by twenty-one out of thirty-six treated with carbolic acid.

Ambulatory Dressings in Fractures of Thigh and Leg.

Professor von Bardeleben (Berlin) said that the ambulatory method of Hesselig is now much simplified, the former complicated and rather expensive apparatus being replaced by plaster dressings only. The broken bone is put on a splint till the swelling has reached its acme, and then a very well-fitting plaster dressing is applied, which, being supported by the prominences of the malleoli and the pubic bone, keeps the ends of the broken bone in apposition. A few days after the injury the patient may try to walk and nearly always succeeds in so doing. During last year thirty-nine out of forty-five fractures of the leg and sixteen out of twenty-three

fractures of the thigh were treated in this way. The method, of course, requires constant attention and supervision, and is therefore only possible in hospital.

Appendicitis.

Professor Czerny (Heidelberg) said that the mucous membrane of the vermiform appendix often became abraded by faecal concretions, and that bacteria easily penetrated into the small ulcerations caused thereby. Appendicitis, when acute, may arise from the presence of bacterium coli, and when chronic from the tubercle bacillus or actinomyces. Patients who had to all appearance recovered spontaneously were apt to suffer at a later stage from severe pains, constipation, vomiting, &c., and the appendix had often to be removed afterwards. The prognosis is good, those cases excepted where the appendix is fixed by agglutination to the surrounding tissues.—Professor Krönlein (Zürich) remarked that he had sometimes seen a faecal fistula follow this operation.—Dr. Kürte, Dr. Israel, and Dr. Rotter confirmed this statement.

The After-treatment of Laparotomy.

Dr. Reichel (Würzburg) said that formerly opiates were invariably given after laparotomy, but that at present even laxatives were prescribed in order to remove pyogenic bacteria and their products. Opiates should not be given after simple operations, but they were useful in cases where the intestines were irritated or loosened during the operation; also when symptoms of slight ileus appeared opiates should be tried at first, and if the symptoms do not disappear very soon the peritoneal wound should be opened up. Hemorrhage and peritonitis after the operation also require the peritoneum to be reopened.

SITTING ON APRIL 20TH.

The Sterilisation of Catgut.

Dr. Lauenstein (Hamburg) said that he had found several kinds of bacteria in catgut sold as sterilised. He especially mentioned bacillus subtilis, staphylococcus albus, and micrococcus tetragonus. Suppuration, he was sure, often arose from catgut sutures. In thirty-five out of 149 specimens of catgut he was able to cultivate the bacteria on gelatine. Most germs were present in catgut sterilised by a dry process.—Professor Kocher stated that in his operations for goitre primary union was obtained in only 35 per cent. of the cases when sterilised catgut was used, but in 85.7 per cent. when sterilised silk was used. He has now completely abandoned aseptic sutures, and only employs silk made antiseptic by an alcoholic solution of bichloride of mercury. Since adopting this method he has obtained primary union in every case. The question being very important Professor Kocher suggested the making of a collective investigation, and his proposition was adopted.

Anæsthetics: the Collective Investigation.

Professor Gurlt (Berlin), the secretary of the Congress, read the report on the above subject. The collective investigation has now been going on for five years. This year 52,677 new cases were reported, of which 31,803 were chloroform narcosis with 23 deaths, and 15,712 were ether narcosis with 5 deaths. In 2148 cases narcosis was produced by a mixture of chloroform and ether, in 1554 by the so-called Billroth mixture, in 1425 by ethyl bromide, and in 34 by penthal. The use of ether has much increased. The mortality from chloroform seems to be much greater than that from ether; but very often grave disorders of the respiratory organs, such as pneumonia and bronchitis, result from the inhalation of ether, and death from those complications ought to be regarded as equivalent to death under anæsthetics. Ether was especially harmful after laparotomy.—Dr. Schleich (Berlin) explained his theory of the action of anæsthetics. According to him they are more dangerous the more their boiling points differ from the temperature of the body. He has devised an anæsthetic mixture (chloroform and petroleum ether) whose boiling point is the same as the temperature of the body, and states that he has obtained excellent results, all the disagreeable symptoms (vomiting, &c.) being absent.—Dr. Rosenberg (Berlin) recommended that the mucous membrane of the nose should be brushed with a solution of cocaine before the commencement of the narcosis.—Dr. Rahn (Frankfurt) gave a warning against the use of chloroform near a gas-light, as ethylene chloride is formed.

The Agglutination of Serous Membranes.

Dr. Graser (Erlangen) said that when two serous membranes are put together the agglutination can be divided into

three stages. In the first a small exudation of fibrin takes place, in the second the exudation is increased and the endothelial cells diminish, in the last stage these cells completely disappear and a thick fibrinous stratum lies between the membranes. This fact is in accord with Alexander Schmidt's opinion that fibrinous exudation is always connected with a lesion of the cells. All antiseptic preparations influence the cells and consequently are apt to accelerate the agglutination of serous membranes.

Vaginal Hysterectomy.

Professor Landau (Berlin) submitted a report on Vaginal Hysterectomy after Pean's method.

Resection of the Rectum.

Dr. Schede (Hamburg) described this procedure for the relief of syphilitic stricture. He has performed fourteen such operations, of which twelve were successful. In two cases the operation could not be completed, the ulcers being too high above the anus. This operation is much more difficult than that for carcinoma, but he nevertheless prefers it to colotomy.

At the last sitting Professor von Bergmann was elected President for next year, when the twenty-fifth anniversary of the Congress will be celebrated with great distinction. Professor Thiersch (Leipzig) whose lamented death is recorded in another column, was appointed an honorary member. The attendance of surgeons was much greater than at any of the former meetings, and the company included two well-known British surgeons, Professor Alexander Ogston (Aberdeen) and Mr. Arthur Barker (London).

THE ROYAL SOCIETY CONVERSAZIONE.

It was evident from a glance at the exhibits at the annual soireé of the Royal Society, held on Wednesday last, that the work of the past scientific year had been allocated chiefly and equally to chemistry and electricity. Indeed, the exhibition of 1895 may be regarded as affording a striking instance of the overlapping of these two sciences, and of how every year they are becoming more and more locked up in each other. To the analytic power of electricity, for instance, was largely due the discovery of argon, and the knowledge of the existence of argon led to the discovery of helium, so that in less than six months two most important members have been added to the chemist's list of elements by the aid of this mysterious and marvellous force. The exhibition of helium and argon was naturally expected by everyone, and no one could have been disappointed, for Professor Ramsay was able to show the spectra of argon extracted from air, and also of a mixture of argon and helium extracted from the Norwegian mineral, clèveite. An exceedingly pretty experiment was shown by Professor Roberts Austen of the Mint, consisting of an ingenious arrangement by which the effect of the enormous heat of the electric arc upon refractory metals could readily be seen projected upon the screen. Thus the melting of chromium and other refractory metals in the electric furnace was demonstrated. The temperature for this purpose approaches 3000 C. The chief point of interest in the exhibit of the metals of the platinum group by Messrs. Johnson Matthey and Co. lay in the fact of the great value of the separated metals. Thus a native platinum nugget weighing 158 grs. was on view, while close by it was a palladium ingot 1000 grs. in weight and of the value of £7000, which had been separated from an amount of gold and platinum of the value of two and a quarter millions of money. Oddly enough, Professor Lewes's exhibit illustrating the preparation of acetylene gas (240 candle power) from calcic carbide by merely acting upon it with water, and which is obtained by fusing carbon and lime together in the electric furnace, stood side by side with the interesting specimens collected by Major Cardew in connexion with the recent street explosions caused by electric mains. Specimens of the deposit containing sodium and potassium were shown. Of interest to medical men was the electrical cabinet for use in the wards of a hospital exhibited by Sir Benjamin Ward Richardson. The cabinet contains, in a comparatively small space, all that is required in the wards of a hospital. It is easily movable from bed to bed, and supplies, as required, a continuous and measurable current, an intermittent.

current, a light with reflector for illuminating the throat, and an electric cautery. It is also furnished with a Hughes' electric balance to serve as an aconometer. The current may be supplied from the main which lights the hospital. The cabinet has been constructed by Messrs. Faraday and Sons, under the direction of the exhibitor, for the use of the London Temperance Hospital.

The possibility of the transmission of infection by flies was admirably demonstrated in the series of cultures by Mr. W. T. Burgess. In his experiments flies were placed in momentary contact with a cultivation of *bacillus prodigiosus* (or other suitable chromogenic organism) and allowed to escape into a large room. After some time they were recaptured and caused to walk for a few seconds over slices of sterile potatoes, which were then incubated for a few days. The experiments showed that the flies' tracks on the potatoes were marked by vigorous growths of the chromogenic organism, even when the flies spent several hours in constant activity before they were recaptured. The use of pathogenic organisms in these experiments would be attended with obvious dangers, but the result obtained with harmless microbes indicate the constant risks to which flies may expose human beings, and the necessity of preventing their entrance and subsequent exit in infectious wards was emphasised.

Other exhibits that should be noticed in our columns were the drawings of enlarged finger-prints by Mr. Francis Galton, F.R.S., illustrating the foundation of the finger-print method lately adopted in the police department for ascertaining, first, whether an unknown and unsuspected person is an habitual criminal; and, second, for verifying doubtful identity. Lastly, a living specimen of the *melapterurus electricus* from the River Senegal was shown by Professor Gotch, and during the evening the shocks of this extraordinary animal were conveyed by means of placing the fish in a net lined with tin-foil to several of the company present, while the disastrous effect of the contact of this electric fish with gold fish was also shown. Among the large company received by the president, Lord Kelvin, in the reception room were the Duke of Saxe-Coburg and Prince Alfred of Saxe-Coburg-Gotha, the French Ambassador, the Marquis of Salisbury, and, it need hardly be added, most of the leading representatives of the various branches of science.

SANITATION AT BELGRADE.

It will be remembered that when the International Congress of Hygiene and Demography met at Budapest last year an excursion to Belgrade and to Constantinople was organised. We described at the time the enthusiastic reception given to the congressists at Belgrade and the eloquent speeches made in favour of sanitary reform. So cordial was the reception and so eager did the local authorities and public seem to be in the cause of sanitation that, on returning from Constantinople, our representative again stopped at Belgrade, and was thus able to forward us some account of the sanitary condition of that city.¹ The Servian press gave the fullest possible publicity to our criticisms. This propaganda work has borne good fruit. Schemes of drainage that had for long remained dormant were brought out from among the municipal pigeon-holes, and an engineer, M. Maresch of Graz, was engaged to go over these plans and devise if possible a new and better combination. This done, the municipality determined to submit these different schemes to a small committee of experts, and selected for that purpose firstly Mr. W. H. Lindley, chief engineer of the Public Works Department at Frankfurt-on-Main, who enjoys a European reputation and is the author of the drainage schemes of several large towns; as the drainage scheme must be combined with the construction of embankments to protect the town from the danger of flooding, Professor Zschokke of Zürich, who has built embankments and docks at Rome, Genoa, La Rochelle, Bordeaux, &c., was the second expert chosen to deal with the sanitary interests of the town in a less technical but in a broader and general sense; whilst Mr. Adolphe Smith was selected as the third expert. These gentlemen met in Belgrade during the course of April and examined the plans submitted. There were in all three plans—one submitted some years ago by an engineer from Berlin,

another by an engineer from Mannheim, and, finally, the modifications and alterations of these plans by M. Maresch. The examination of these schemes by the committee of experts has, practically speaking, resulted in the drawing up of a fourth plan. Without entering upon the many details and complications involved by this problem, it may be briefly stated that Belgrade is, for the most part, built on a promontory overlooking the Save and the Danube. The greater part of this promontory consists of a hill some 300 feet high, with ample falls towards the Danube or the Save; but at the base of this hill there is on both sides a strip of low-lying ground which represents about 30 per cent. of the total area it is proposed to drain. To further complicate the situation the level of the water in both rivers varies very considerably according to the time of year, so that a system of drainage which is possible at one season is impossible at another. A height of 66.24 metres above the level of the Adriatic is the zero of the Save. The lowest water-mark ever known there has been 45 centimetres below this zero and the highest water-mark 8 metres above—at least, this was the height attained during the floods of 1888; but this year the record has been beaten to the extent of 2 centimetres, and this while the committee of experts was sitting, so that they were themselves able to see the maximum difficulty known to history. The water then attained the level of 74.26 above the Adriatic, or 8.02 metres above the zero of the Save. If we consider that the sewers and drains must be laid deep in the earth so as to prevent freezing during the very rigorous weather of the winter, houses should not have been built at a lower level than 80 metres, whereas a vast number are on levels of 70 to 72 metres. The drains of these quarters will, therefore, be below the high water-mark.

The municipality entertains strong objections to any sewer outfalls on the Save side, where it is intended to establish bathing stations and where the back currents caused by the Danube might drive the sewage back upon the town. M. Maresch had conceived the bold idea of piercing a tunnel through the hill on which the greater part of Belgrade is built so as to deliver the sewage of the Save side into the Danube. The committee of experts endorsed this proposal, but suggested that the tunnel should be deeper and longer so as to take all the sewage of the Save side. On the other hand, at this depth the outfall will for about sixty days of the year be too low to empty into the Danube. At a height of 80 metres there will be main sewers collecting all the sewage from the high parts of the town, and these can empty into the Danube at all conditions of the water. During the sixty days it will be necessary to pump up the sewage from the low-lying levels into this higher level system. Such, in a few words, is the method proposed for overcoming the local topographical difficulties. The committee of experts further indicated what methods of drainage should be applied to connect the houses with the sewers, and what by-laws should be enacted so that these works might be properly controlled and rendered efficacious. The plans submitted were all based on the combined system—that is to say, on the admission of rain water into the sewers, with the necessary overflows for storm water. It is perhaps unfortunate that there was no scheme on the separate system, by which the sewage and the rain water would be dealt with separately, for it would have been interesting to see what advantages this rival system could have offered in the peculiar circumstances under which Belgrade is situated. The plan proposed, however, is simple, devoid of complications, and easily applied. It is calculated that the study of the details will take a year and the construction of the sewers about five years. Thus in five or six years Belgrade may become in this respect a model town of Eastern Europe. How greatly this will be to the credit of the capital of Servia can only be realised by those who know something of Servian history. It must be remembered that Servia only acquired its independence when the Turks left Belgrade in 1867. Thus this town has not had more than twenty-eight years of free municipal existence. Even then Servia continued to pay tribute to the Sublime Porte till the war of 1876 broke out. The Pashalic of Nisch was only obtained through the Berlin Treaty in 1878, and Servia was not proclaimed and recognised as an independent kingdom before 1880. These dates show that Servia is a totally new country, and yet it is already eager to carry out proper drainage works and to enforce the most progressive sanitary principles. How many much older countries have failed to show such a practical appreciation of sanitation?

¹ Vide THE LANCET, Dec. 22nd and 29th, 1894.

THE ROYAL ACADEMY.

THERE is a curious want this year of really great pictures. An uninteresting evenness pervades the galleries, and some would say that the average is high. This is true in a sense, for examples of bad drawing are few and are confined for the most part to the works of the Academicians. Composition, too, with the same exception, has been successfully studied. In two particulars only is there no improvement. Colour is, if possible, more inharmonious than ever, many of the more important pictures—as, for example, the President's "Flaming June" and Mr. Tadema's "Spring"—being particularly noticeable in this respect. The choice of subjects is equally unfortunate, the number of death-bed scenes—all, fortunately, as unlike the real thing as possible; the number of children at their mothers' knees, of allegories—with ghosts, angels, or fairies, as the case may be; and of Andromedas, Ariadnes, Judgments of Paris, and other classical subjects, being positively monotonous. There appears to be very little sculpture this year, though there are two or three of the nude figures which, if we mistake not, Mr. Onslow Ford made the fashion a few years ago. He exhibits an attenuated girl in bronze, very well modelled, but very ill-nourished, and entitled "Echo." Mr. Thorneycroft's recumbent figure of the late Bishop of Carlisle should not be overlooked. There is a curious drawing which looks like tapestry in the sculpture room. It is one of Mr. Richmond's designs for the decoration of St. Paul's (1713). The water colour room is well filled, and we observe a very clever portrait by Mrs. Jopling (914); a curious, highly finished "Cinderella," by Mr. Southall (962); and "Quietude," an eccentric study of a head, with Dürer's "Melencolia" as a background, by Mr. Lucien Levy (971). "An Alien," a lovely figure, highly finished, but very small, is by Mr. Bulleid (1024). Mr. Clifford makes a new departure in his "Bric-à-brac Shop" (1082).

If we take the galleries in order, omitting portraits, we shall find three or four pictures worth looking at in the first. These are "Spring," by Cecil Rea (38); "Evening," by Mr. Leader; "St. Stephen," by Sir J. E. Millais (18); and "The Fisherman and the Jin," by Mr. Prinsep (25). "The Pot of Basil," by J. L. Gloag (53), is powerful enough but too eccentric, and Isabella cannot have the normal number of vertebrae in her spinal column. In the second room we find Mr. Waterhouse's "St. Cecilia." She is represented in a "walled city on the sea," asleep with two angels playing before her. The artist has experimented and striven with all his might to attain harmony of colour, but has failed, yet his picture in many ways deserves its "place of honour." Mr. Byam Shaw errs in the same manner, but less completely, and his scene from the "Blessed Damozel" (110) has some of the richness of a manuscript illumination. The President's "Maid with the Golden Hair" (139) is pleasing and very complete. Mr. Storey's "Coming Events" (40) has his usual prettiness and the landscape part is good, but not so good as in his "November Sunshine" (81).

In the Great Room the place of honour is filled by Mr. Briton Rivière's "Phœbus Apollo" (160) driving a team of lions in a chariot. We question if he will ever succeed in getting back the foot and leg he has extended over the front of the chariot, but the whole picture is brilliant and spirited to a rare degree. "Ruth" (225) and "Rachel" (216), by Mr. Goodall, are much alike in hardness and dull colouring, but are correctly drawn. It is not possible to praise the picture of an ugly, bloated boy, with a crooked mouth, which Mr. Watts labels "The Outcast: Goodwill" (258), nor is it possible to make out the meaning of the name. There are several fine landscapes in this room, but both Mr. MacWhirter's and Mr. Peter Graham's suffer from wooliness. "Glen Orchis" (201), by Mr. Henry Moore, will be admired, as will two views by Mr. Hook, and Mr. Brett's reminiscence of his native cliffs (232), which is rather spoiled by a spotty foreground. We should also notice the President's graceful "Lachrymæ" (182), and Mr. Poynter's charming little "Ionian Dance" (270), is both well drawn and well finished.

There is little to delay us in the fourth room, but "A Priestess," by Mr. Godward, is firmly handled and not without beauty (304). In the fifth gallery we may pause at Mr. Brett's "Isles of the Sirens" (409) and at Mr. Shannon's cold and unpleasantly anæmic Portrait of a Lady (410). In

gallery six there is a tremendous and overpowering painting by Mr. Herkomer, representing a Bavarian Burgomaster and his Councillors, life size (436). In gallery seven we see Mr. Croft's picture of Napoleon Cheering on his Troops at Waterloo (499). "The Bayswater 'Bus," by Mr. George Joy, is clever, and includes some pretty faces, but there are obvious difficulties in the view. "Evening Glow" (534) is one of Mr. Leader's best pictures this year, though the trees and the watery meadows have so often done duty before. In the eighth gallery we have a fine sea-piece by Mr. Somerscales, "After the Gale: Taking to the Boats" (593), but Mr. Wyllie in a large painting fails to make the Tower Bridge picturesque (611).

In the ninth gallery we have the usual show of small works this year by Messrs. Moore, Dillon, Legsdall, Gow, Mrs. Alma-Tadema, and Miss Montalba. In the next room is a pleasant "Offer of Marriage," by Mr. Sadler (776), and a curious but powerful interior of a Joss House, by Mr. Wetton (761). In the eleventh gallery we must pass over Lady Butler's "Scots Greys on the Morning of Waterloo" (853), and a battle piece by Mr. Caton Woodville (869), and go on to a very powerful Snow Scene by Mr. Farquharson (873). "Toddy at the Cheshire Cheese," by Mr. Dendy Sadler (887), represents a cleverly painted group of old toppers, and is in the artist's best style.

A longer and more careful examination than we have had time to bestow on this year's exhibition will no doubt reveal much that we have missed, but the foregoing notes give only the impressions of a first glance.

CITY HOSPITAL, BIRMINGHAM.

ON the invitation of the chairman of the Health Committee, Alderman Cook, a number of gentlemen interested in the sanitary condition of the borough attended at the site of the new hospital at Little Bromwich on April 24th. So many responding to the request, it was found necessary to organise the visitors into three parties, under the guidance respectively of Alderman Cook, Alderman Dr. Barratt, and Mr. Councillor Lancaster. About 180 were present, lunch being provided by the chairman, whose practical knowledge, sound judgment, and constant attention have contributed largely in making the new scheme successful. The present hospital may be looked upon as one of the most perfect of its kind, replete with every modern arrangement and appliances of the most recent kind; indeed, no efforts or money have been spared to bring it to a degree of completeness which will justify the labour spent upon it. Appended is a plan of the hospital with explanatory notes taken from the programme of the day's proceedings.

The hospital has been erected for the treatment of small-pox cases. It is situated on the east side of the city, about three and a quarter miles from the centre of the town and about 500 yards from the city boundary. The site is about twenty-four acres in extent.

A. Entrance lodge, a red brick building relieved with stone, with half-timbered gables, a covered porch, and a vestibule communicating on one side with a reception-room for visitors or others making inquiries, and on the other with the porter's residence and yard, from which access to the gas and water meters is obtained.

B. Receiving ward. This consists of a single room, with a bath-room leading therefrom, and a small enclosed yard and offices. Here patients are examined and stripped of their clothing, which is sent at once to the disinfecting stations to be purified before being placed in the store connected with the discharging ward. The patients are then taken either directly into one of the pavilions to undergo treatment, or if any doubt exists as to the nature of the case they are placed in the isolation pavilion and kept there for further observation.

C. The isolation pavilion is situated on a by-road; it is arranged for males and for females, and consists of a number of small wards with one, two, or three beds in each as required. The access to each ward is from the open air, but under a covered glass verandah. Special bathing and other sanitary arrangements are made, all securing perfect isolation.

D. Official and administrative departments. This block is divided into three sections, the central containing the medical quarters and matron's apartments, the left-hand side

containing the steward's apartments and stores, messroom, kitchen, and kitchen yard, and the right-hand side containing the servants' accommodation, recreation room, matron's stores, and the officers' laundry. The various departments are so arranged in this block that, whether stores, food, or medicines are required, they are delivered from the lobbies on either side to the attendants or nurses, and conveyed by them directly down the asphalt avenue to the pavilions or other blocks, the person conveying it not requiring to enter this building beyond the serving window. In this block, too, in the lobby leading to the officers' quarters, is placed the telephone, by which communication can be made with the various blocks, and also with the Council House and the general telephone system of the city.

E. The pavilions are four in number. Each has twenty-four beds and consists of two wards 72 ft. by 30 ft., with an allowance of air space to each patient of over 2000 cubic feet. At the ends of the wards are the bath-rooms and water-closets, fitted up with the latest sanitary improvements. Between and connecting the two wards which constitute each

pavilion is the entrance hall, with a duty-room overlooking each ward; also food, pantry, linen, fuel, stores, &c. The wards are heated by open-fire, down-draught stoves, the bath and water-closet blocks being heated by high-pressure radiators from the steam mains. The floors are laid with oak blocks polished with hard paraffin and turpentine. The lighting is effected from the ceiling, the products of the combustion being kept entirely out of the wards.

F. The servants' quarters and cottages for the out-door officers contain kitchens, general sitting-rooms, &c, and a small bedroom. Each one is thoroughly heated, lighted, and ventilated.

G. Laundry, &c.—At the extreme rear of the centre of the site are situated the laundry and disinfecting yard with incinerator, perfect isolation being preserved. The steam disinfecter is of the Washington Lyons type. In the process of disinfection the articles are taken to the yard on the infected side and placed in the jacketed steam receiver. This is closed

up and steam at 20 lb. pressure is introduced. The steam is then exhausted, and the jacket, which is superheated, immediately evaporates all the moisture. The receiver is opened on the disinfected side, the articles being withdrawn thoroughly dry and forwarded to their various destinations. The only means of communication between the infected and the disinfected sides is a glass pane through which the attendants can communicate by speaking loudly. The lower level of this part is apportioned to the engineer's shopping, boilers, coal stores, storage, stabling, ambulance house, &c.

H. In the far corner of the site, on a side road, are placed the mortuary and post-mortem room, fitted up with all the necessary appliances.

J. Discharging ward. This is a small two-storeyed building, with necessary dressing- and bath-rooms. On the first floor, approached by an external doorway, is the clothes store, in which disinfected clothing is stored until required by out-going patients.

The dotted block K shows the proposed position of the nurses' home; and the blocks marked L show where additional pavilions can be erected if necessary.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary comitia of the College was held on April 25th, Sir J. Russell Reynolds, Bart., President, being in the chair.

John Henry Bryant, M.D. Lond., Louis Leopold Jenner, M.B. Oxon., Theophilus Nicholas Kelynaek, M.D. Vict., and William Barnett Warrington, M.D. Lond., were admitted to the Membership.

Licences were granted to 130 candidates who had passed the recent examinations of the Conjoint Board.

Communications were read from the Royal College of Surgeons of England reporting the proceedings of the Council of that body, and from the Secretary to the British Institute of Preventive Medicine asking the College to nominate a representative to its Council. The request was referred to the Council of the College for consideration.

The following Members nominated by the Council for the Fellowship were balloted for and duly elected:—Frederick William Andrewes, M.B. Oxon.; James Calvert, M.D. Lond.; William Radford Dakin, M.D. Lond.; William Heaton Hamer, M.D. Camb.; Frederic Harry Haynes, M.D. Lond. (Leamington); Patrick Manson, M.D. Aberd.; Francis George Penrose, M.D. Lond.; Robert Michael Simon, M.D. Camb. (Birmingham); Frederick John Smith, M.D. Oxon.; Frank Joseph Wethered, M.D. Lond.; Dawson Williams, M.D. Lond.

The quarterly report of the Finance Committee was received and adopted.

The report from the Committee of Management dealing with the subject of the examinations for the Diploma of Public Health and referred back to the committee at the last meeting was presented in an amended form and adopted.

In accordance with the recommendations of this report the Syllabus for Part I. of this examination will now be as follows, every candidate being required to undergo this practical examination in bacteriology:—

1. Physics in their application to health; with reference to—
 - (a) Warming and Ventilation; (b) Water Supply, Sewerage, and Drainage; (c) Sanitary Construction.
 2. Meteorology in Relation to Health.
 3. Chemistry, with special reference to Food, Air, Soil, and Water.
 4. Microscopical Examination, as applied to Air, Food, and Water.
 5. Bacteriology, including the cultivation and recognition of Micro-organisms.
 6. Geology and Soil in Relation to Drainage and Water Supply.
- The course of lectures on Pharmacology and Therapeutics delivered by Dr. J. B. Bradbury, Downing Professor of Medicine at the University of Cambridge, was recognised as fulfilling the requirements of the Board. On the application of the Dean of the Faculty of Medicine of University College the course of Clinical Demonstrations in Lunacy, given by Dr. W. J. Mickle at the Grove Hall Asylum, Bow, was recognised so long as he shall hold the Lectureship on Mental Diseases in that College. The Dundee Royal Infirmary was added to the list of hospitals recognised by the Board.

A further report was received from the Committee of

Management, (a) indicating the range of the Third and Fourth Examinations under the new regulations; (b) recommending that every candidate be admitted to a separate examination in Ophthalmology at the Final Examination; (c) explaining the procedure adopted by the committee in dealing with applications for the recognition of institutions as places of instruction in chemistry, physics, practical chemistry, and biology; (d) recommending the recognition for such purpose of the Higher Grade Board School, Victoria-road North, Southsea; Wellington College, Wellington; the Grammar School, Bristol; and the Birkbeck Literary and Scientific Institution; (e) recommending the recognition of the course of instruction for the Diploma of Public Health at the Westminster Hospital; and (f) recommending that the City of London Hospital for Diseases of the Chest be recognised as a place of study during the fifth year of the curriculum.—The report was adopted by the College.

A report from the Laboratories Committee, detailing the work being carried on in the laboratories, was received and adopted.

The quarterly report of the Examiners for the Licence was received and adopted.

CHOLERA.

THE revitalisation of cholera at the present season, after the epidemic has been apparently dormant and hibernating, as it were, for some months, is an interesting and, as subsequent events may prove, a significant fact. As we have frequently said, cholera often makes its earliest manifestation towards the end of March and the middle of April, and so it has proved in the present year. We learn from St. Petersburg that 22 cases occurred, 13 of them fatal, in the province of Podolia, in Russia, between March 24th and April 13th, while in the province of Volhynia there were 112 cases and 36 deaths between March 17th and April 6th.

The outbreak of epidemic cholera among the Mecca pilgrims at the quarantine lazaretto of Camaran on the Red Sea is naturally giving rise to a good deal of anxiety in Egypt. The first cases were reported at the end of March, and the number of attacks had risen to thirty at the end of a week. As many as 11,000 pilgrims had passed through on their way to Djeddah, and the lazaretto was at the date of the last report occupied by some 2000 pilgrims. Within the next few weeks the bulk of the pilgrims will be returning, and it has been officially declared that the disease has broken out at Mecca. The chief of the Camaran lazaretto has proposed to the Supreme Sanitary Council in Constantinople to stop the pilgrimage from India and the Dutch Colonies, but the Sultan is, on religious grounds, opposed to this. It is worth remarking that the Indian authorities allege that the disease was not conveyed from that country, for the pilgrims were free from all disease when they embarked and no cholera appeared among them until after they had been quartered in the quarantine lazaretto at Camaran. There can be no doubt, if all that is said of it be true, that Camaran is a hotbed for developing the disease, and the present outbreak is attributed to the bad condition of the lazaretto, the overcrowding, and the impurity of the water supplied to the pilgrims there and en route to Mecca. A radical change is required at Camaran and throughout the province and at Mecca itself. It is understood that the present governor-general is instituting a number of sanitary reforms. We should like to hear that the Sultan had sent some sanitary expert from Europe or this country to advise as to the necessary measures to be undertaken. Cholera does not, as a rule, spread from Arabia and Egypt to this country, notwithstanding that it is the shortest route, and we are not apprehensive on that ground. As regards Egypt, if the disease spreads to and appears at Cairo we trust that no time will be lost in moving the British troops up to Mokattam, which was done with some of them on a previous occasion, with the result that those quartered there escaped the epidemic altogether. The difficulty about encamping troops there is the want of water.

Some vessels have arrived in the Thames with a history of having had cases of cholera or choleraic diarrhoea on board.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Fever in the Mold Urban District, by Dr. WHEATON.—Mold was evidently the subject of an official inspection because typhus fever was suspected at Whitehall to be prevailing there; but the disease was enteric fever, and it was found to exist under circumstances of filth and sanitary neglect which we hope, and feel sure, are very exceptional. The houses affected were often squalid and "extremely filthy" both within and without; in fact, the main burden of the descriptive portion of the report is as to filth in various forms and degrees, the whole making the reader wonder whether there could in such a place be anything corresponding to a sanitary authority, sanitary administration, and sanitary officers. The only relief to this part of the story is the statement that the medical officer of health, with the aid of the Poor-law authority, turned some of the affected dwellings into hospital, nurses' home, and mortuary respectively, and that this action taken in the emergency is credited with having had much to do in staying the further diffusion of the infection of this "filth disease." Mold has for several years past suffered from enteric fever. It cannot be attributed to its water-supply, neither was it found to be due to milk. Indeed, Dr. Wheaton comes to the conclusion that emanations from defective sewers, and midden-prives infected by reason of having received the discharges of some of the sick, together with the generally careless habits of the people, such as is almost everywhere found where the surroundings of people are filthy, were the real cause of the spread of the disease. Since a previous official visit in February, 1894, the authority have applied for a loan for the purposes of a system of sewerage, and it is to be hoped that when this is carried out a water-carriage-system which will ensure the immediate removal of excreta from the neighbourhood of dwellings will lead to the initiation of some substantial improvements. But even before then gross nuisances, dwellings unfit for human habitation, and the like should be dealt with by the authority.

On a Prevalence of Enteric Fever at Desborough, by Dr. W. W. E. FLETCHER.—Desborough is a small urban district of some 2900 inhabitants near Kettering, and it has suffered severely from enteric fever. During 1890 and up to March, 1891, there were no less than 188 attacks, of which 23 terminated fatally, and from that time forward until late in 1894, when the medical officer of health reported a fresh prevalence, the disease has been all but epidemic. All the ordinary and all the possible causes of enteric fever were evidently looked into with care; but it is to the water-supply that Dr. Fletcher attributes the unhealthy and unfavourable state of Desborough. The wells are sunk in open and porous soil which rests on clay; they are filled in the main by surface water and by means of privy-middens and other sources of filth which admit of soakage into the same surface soil; the water-bearing stratum is constantly subject to fouling. The natural flow of the water has also conducted to the result, for in passing to the main body of the village it would wash along with it the soakage of filth from another part, and this latter part is that in which the first case of enteric fever occurred. In dealing generally with the sanitary administration of Desborough, Dr. Fletcher is able to point out that there are able but underpaid sanitary officers, whilst the authority is principally noted for negligence and indifference to the advice of their officers, and this notably in the matter of the need for providing a wholesome water-supply. They have no system of notification, they do not register cowhouses or slaughter-houses, and they avoid taking powers which it is optional with them to do without. Dr. Fletcher's report is well compiled, is clear and lucid, free from any approach to verbosity or undue length, and being a plain, simple story of the facts as elicited it ought to be appreciated by every member of the district council and to move them to act without delay, especially in regard to the question of water-supply.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Leeds Urban Sanitary District.—Dr. Spottiswoode Cameron's annual report for 1893 contains much interesting matter. He deals in a very detailed manner with the subjects of which he treats, and anything like a full review of the report our space will not permit. The position which Leeds occupies among the nine great towns of the United Kingdom, each with a population of 250,000, is, in the matter of general death-rate, a satisfactory one, coming as it does fourth on the list. The death-rate for 1893 was 22·3 per 1000, a rate in excess of that for the three preceding years, but which excess was more than accounted for by the increased number of deaths from measles and diarrhoea. When the Leeds death-rate is compared with English towns alone having at the last census populations of 250,000 and over, it is found that Birmingham is the only town which in 1893 had a rate less than Leeds; and in pointing out this fact Dr. Cameron pays a just tribute to the praiseworthy efforts of Birmingham to deal with her unhealthy areas. In the report before us the vital statistics of Leeds are discussed in considerable detail, and Dr. Cameron has endeavoured to arrive at a trade correction factor for the district. Part II. of the report deals with special diseases, and under each disease the time, age, and sex incidence are considered, as well as the sanitary condition of the invaded houses. Dr. Cameron gives a very interesting account of the progress of small-pox in Leeds during 1893 and of the isolation accommodation provided for the cases. The old small-pox hospital was, on the erection of a new temporary hospital, intentionally burned down; there was, it appears, some suspicion that the hospital was acting as a focus for the spread of the disease. Persons exposed to the infection of small-pox were isolated in a cottage shelter belonging to the corporation, and out of 1458 persons so housed 83 developed small-pox within a fortnight. The following figures, showing the attack-rate amongst those isolated at the shelter, are instructive. Of 129 cases in which there was no evidence of either vaccination or primary small-pox 18 per cent. developed the disease, while of 1196 who showed some signs of vaccination only 5 per cent. did so. Of 40 who had previously had small-pox none were attacked, while of 93 persons concerning whom no information was forthcoming 3 developed the disease. In discussing the influence of vaccination upon recovery among the 586 cases passing through the hospital in 1893, Dr. Cameron states that the mortality among 42 said to have been vaccinated, but showing no marks, was 9·5 per cent., among the "unvaccinated" 28·2 per cent., among the imperfectly vaccinated 5·3 per cent., and among 257 cases who showed signs of having been properly vaccinated nil. The influence of the number of cicatrices is shown below in a table drawn up by Mr. A. E. Pearson, resident medical officer to the City Infectious Hospital:—

Showing the Number of Visible Vaccination Cicatrices in each Case, the Number of Deaths, and the Mortality per cent.

	Cases.	Deaths.	Mortality per cent.
Six cicatrices	3	—	Nil.
Five cicatrices	2	—	Nil.
Four cicatrices	89	—	Nil.
Three cicatrices	144	3	2·0
Two cicatrices	184	4	2·1
One cicatrix	76	6	7·8
No cicatrices	88	17	19·3
Total	586	30	5·1

Dr. Cameron has made a most exhaustive analysis of the deaths from diarrhoea in Leeds during 1893, and we strongly recommend this part of the report to the notice of our readers. The conditions of the houses in which fatal attacks occurred have been thoroughly gone into, and it appears that 79·8 per cent. of the fatal cases were attacked in houses without a through draught. It is shown, too, that "fatal diarrhoea occurred disproportionately in the smaller dwellings, and that amongst them it selected as a rule those most crowded." We are unable to touch upon all the interesting points raised by Dr. Cameron, but we reproduce a table with regard to the feeding of infants and diarrhoeal mortality, which we feel sure will be of interest.

Showing in percentages, as to Deaths specially inquired into, the Mode of Feeding of 153 Infants under one year of age, whose Deaths were registered as due to Diarrhoea in the Six Weeks ended Sept. 30th, 1893.

Ages.	Cases inquired into.	Per cent. of the 153.	Percentages of those dying at different ages fed—				
			On mother's milk only.	Partly at breast.	Not at breast at all.	By bottle.	Both at breast and bottle.
0 to 3 months ...	41	27	24	20	56	71	17
3 to 6 months ...	55	36	16	13	71	76	11
6 to 9 months ...	34	22	3	9	88	91	9
9 to 12 months ...	23	15	30	17	52	61	8
Whole	153	100	18	14	68	76	12

Dr. Cameron has for several years past amassed a vast number of details in regard to the sanitary condition of houses invaded by infectious disease, and the results must one day be of the greatest value in attempts to arrive at legitimate deductions.

Coventry Urban Sanitary District.—The infantile mortality of Coventry continues, Dr. Mark Fenton reports, to be a high one, and there has been no improvement in the rate during the last twenty years. Sanitary science has not yet, he observes, seriously applied itself to the reduction of infantile mortality. In discussing the value of school closure in measles epidemics, Dr. Fenton states that the closing of schools in Coventry has been invariably followed by a marked and significant reduction in the number of cases notified. As instancing this statement the following table for 1894 is given:—

Weeks ending March		Weeks ending April				Weeks ending May		
24th*	31st*	7th*	14th*	21st†	28th†	5th†	12th†	19th†
162	213	275	492	306	260	134	88	42

* Open.

† Closed.

The school in this instance was closed late in the week ending April 14th. As further corroboration of the value of school closure Dr. Fenton supplies figures for 1886 and 1889.

Cases of Measles recorded in 1886.

January to August	81	} Schools opened.
September	361	
October (first fortnight)	186	
October (second fortnight)	111	} Schools closed.
November	10	

Cases of Measles recorded in 1889.

January to June	186	} Schools opened.
July 1st to 25th	629	
July 25th to Aug. 10th	218	
Aug. 10th to Sept. 1st	74	} Schools closed.
September	17	

In Coventry measles is notifiable, but it appears that the sanitary committee have recently been considering the desirability of discontinuing the notification of this disease, owing to the fact that school closure alone has been found effectual in staying the spread of the disease. Dr. Fenton, however, has well advised the committee that until they are in a position to test the effect of isolating the first notified cases in hospital, it can hardly be concluded that notification is of no value.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6734 births and 3829 deaths were registered during the week ending April 27th. The annual rate of mortality in these towns, which had declined in the seven preceding weeks from 35·0 to 20·3 per 1000, further fell last week to 18·9. In London the rate was equal to 17·9 per 1000, while it averaged 19·5 in the thirty-two provincial towns. The lowest rates in these towns were 10·4 in Croydon, 11·3 in Swansea, 12·7 in Cardiff, 13·0 in Derby, and 13·5 in Bristol; the highest

rates were 27.4 in Wolverhampton, 27.6 in Manchester, 28.7 in Norwich, 29.2 in Preston, and 29.3 in Bolton. The 3829 deaths included 327 which were referred to the principal symtotic diseases, against 330 and 336 in the two preceding weeks; of these, 111 resulted from whooping-cough, 85 from measles, 50 from diphtheria, 39 from diarrhoea, 24 from "fever" (principally enteric), 18 from scarlet fever, and not one from small-pox. No fatal case of any of these diseases occurred last week in Swansea or in Birkenhead; in the other towns they caused the lowest death-rates in Bristol, Portsmouth, Huddersfield, and Bradford, and the highest rates in Liverpool, Burnley, Manchester, Plymouth, and Bolton. The greatest mortality from measles occurred in Sheffield, Manchester, Plymouth, and Bolton; and from whooping-cough in Plymouth, Wolverhampton, Liverpool, Bolton, Blackburn, Preston, and Burnley. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 50 deaths from diphtheria included 27 in London, 5 in Manchester, and 4 in West Ham. No fatal case of small-pox was registered either in London or in any of the thirty-two large provincial towns. There were 37 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, April 27th, against 53, 47, and 35 at the end of the three preceding weeks; 12 new cases were admitted during the week, against 7, 9, and 4 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1469 against 1519, 1463, and 1514 on the three preceding Saturdays; 132 new cases were admitted during the week, against 143, 117, and 162 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 398 and 389 in the two preceding weeks, further declined to 341 last week, and were 24 below the corrected average. The causes of 46, or 1.2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Bradford, Newcastle-upon-Tyne, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Bristol, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24.7 and 21.7 per 1000 in the two preceding weeks, further declined to 20.6 during the week ending April 27th, but was 1.7 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15.1 in Greenock and 17.1 in Edinburgh to 24.9 in Aberdeen and 25.6 in Leith. The 594 deaths in these towns included 26 which were referred to measles, 24 to whooping-cough, 13 to diarrhoea, 3 to scarlet fever, 3 to diphtheria, 3 to "fever," and 1 to small-pox. In all, 73 deaths resulted from these principal symtotic diseases, against 88 and 78 in the two preceding weeks. These 73 deaths were equal to an annual rate of 2.5 per 1000, which was 0.9 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 22 to 32 in the three preceding weeks, declined again to 28 last week, of which 8 occurred in Edinburgh, 6 in Glasgow, and 4 in Leith. The deaths referred to whooping-cough, which had been 30 and 17 in the two preceding weeks, rose again to 24 last week, and included 17 in Glasgow and 3 in Greenock. The 3 fatal cases of scarlet fever were within one of the number in the preceding week, and included 2 in Glasgow. The deaths from diphtheria, which had increased from 2 to 7 in the three preceding weeks, declined to 3 last week, of which 2 occurred in Glasgow, where the fatal case of small-pox was also recorded. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 162 and 132 in the two preceding weeks, rose again to 145 last week, and exceeded by 38 the number in the corresponding week of last year. The causes of 32, or 5.4 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29.2 and 29.7 per 1000 in the two preceding weeks, declined to 27.0

during the week ending April 27th. During the past four weeks of the current quarter the death-rate in the city has averaged 32.3 per 1000, the rate during the same period being 18.8 in London and 19.4 in Edinburgh. The 181 deaths registered in Dublin during the week under notice showed a decline of 18 from the number in the previous week, and included 4 which were referred to the principal symtotic diseases, against numbers declining from 12 to 3 in the four preceding weeks; of these, 1 was referred to small-pox, 1 to diphtheria, 1 to whooping-cough, 1 to "fever," and 1 to diarrhoea, but not one either to measles or scarlet fever. These 5 deaths were equal to an annual rate of 0.7 per 1000, the symtotic death-rate during the same period being 1.5 in London and 2.1 in Edinburgh. The mortality from small-pox and from "fever" corresponded with that recorded in the preceding week. The fatal case of diphtheria was the first registered within the city during the current quarter. The 181 deaths in Dublin last week included 18 of infants under one year of age and 58 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from those recorded in recent weeks. Eleven inquest cases and 6 deaths from violence were registered; and 61, or rather more than a third, of the deaths occurred in public institutions. The causes of 9, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR GRIEB has been appointed Instructor at the Depot, Medical Staff Corps, Aldershot, in succession to Surgeon-Major Tyrrell, whose time has expired. Surgeon-Major Reckitt has arrived at Jamaica and Surgeon-Captain McCormack has embarked for Sierra Leone. Surgeon-Captain Thacker has been posted to the Curragh, and Surgeon-Captain Green has been transferred from Birmingham to Dublin. Surgeon-Captain Corcoran has been appointed to the Eastern District on arrival from Malta.

ARMY MEDICAL STAFF.

Surgeon-Major-General James Davis is placed on retired pay; Surgeon-Colonel Francis Henry Welch, F.R.C.S. Eng., retires on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenant Kilkelly to officiate in Medical Charge of the 4th Bombay Cavalry. Surgeon-Colonel Mannsell is posted to the Mhow District. Brigade-Surgeon-Lieutenant-Colonel Gallwey, on being relieved by Surgeon-Colonel Mannsell, returns to Bombay. Surgeon-Colonel T. Mannsell, A.M.S., to be Principal Medical Officer, Chitral Relief Force, vice Surgeon-Colonel W. T. Martin, A.M.S. Surgeon-Colonel W. D. Wilson, A.M.S., to be Principal Medical Officer, Secunderabad and Belgaum Districts. Brigade-Surgeon-Lieutenant-Colonel W. F. Burnett, A.M.S., to be Officiating Principal Medical Officer, Mandalay District and Chim Hills Command. Surgeon-Colonel S. B. Hunt to be Principal Medical Officer, Bangalore and Southern Districts. Surgeon-Colonel D. F. Bateman to be Principal Medical Officer, Madras District. Surgeon-Colonel F. H. Blenkinsop to be Principal Medical Officer, Rangoon District. Surgeon-Lieutenant G. S. McLaughlin, A.M.S., is appointed Staff-Surgeon, Lucknow.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Fleet-Surgeon: E. H. Saunders to the *Edinburgh*. Staff-Surgeons: A. P. Johnston to Chatham Hospital, George S. Smith to the *Blenheim*; R. F. Yeo to the *Nile*; J. Porter to the *Britannia*; H. S. R. Sparrow to the *Calypso*. Surgeons: J. Chambers to the *Minotaur*; R. F. Bowie to the *Britannia*; Alexander Maclean to the *Pembroke* additional; John D. Menzies to the *Halcyon*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Hugh Ransom Bramwell, M.B., the Tynemouth Volunteer Artillery (Western Division, Royal Artillery), to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Surgeon-Lieutenant J. B. Mann to be Surgeon-Captain.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion, the Gordon Highlanders: Surgeon-Lieutenant-Colonel W. R. Duguid resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement. 3rd Volunteer Battalion, the Royal Fusiliers (City of London Regiment): Surgeon-Captain E. G. Younger, M.D., resigns his commission. 2nd Volunteer Battalion, the Lincolnshire Regiment: Surgeon-Captain G. F. England to be Surgeon-Major. 1st Volunteer Battalion, the Cheshire Regiment: Ernest Richard Woody Spratly, Gent., to be Surgeon-Lieutenant. 2nd Volunteer Battalion, the Gloucestershire Regiment: Percy Trenavin Lunn, Gent., to be Surgeon-Lieutenant.

THE ARMY MEDICAL STAFF.

In the second of the series of articles which are appearing in the *Times*, under the heading of "War Office Administration," allusion is made to the changes that have taken place in the medical service in connexion with those which were introduced—mainly in the late Mr. Stanhope's time—in various other departments of the army. Many of these changes in respect of the ordnance factories, artillery and stores, the late commissariat, Army Service Corps, &c. are passed in review and subjected to criticism of an adverse kind. The writer seems to think that the principal feature of the minor military changes of recent years is the destruction of professional *esprit de corps* and the allotment of duties inconsistent with proper training. As regards the Army Medical Staff, with which we are only concerned, it is stated that all have combatant titles, which are socially and officially misleading. It cannot be denied that the indictment is drawn up in sufficiently strong terms. "They [medical officers] may occasionally be seen drilling hospital attendants as if they were infantry soldiers, and their plea to sit on courts-martial will probably soon be admitted. Surgeons-major-general require medical officers attached in a staff capacity to act as the medium of communication between themselves and other departments; and when a heedless young regimental officer is liable to be officially reported for applying to his medical attendant the honoured title of 'doctor' it is clear that all proper professional pride is in danger of being lost. Even the essential requirement of a distinctive uniform has dropped out of sight, and an expert is needed to differentiate the Medical from the Army Staff. In striving to be what he is not the army doctor will inevitably fail in the exercise of his rightful, honourable, and indispensable functions. To fighting rather than to saving life his ambitions will tend. Meanwhile, the necessity for converting naval doctors into admirals, post-captains, and commanders does not appear to have yet arisen. Medical science in the navy does not seem to be a source of shame to its professors, who, moreover, wear distinguishing marks well understood by the navies of all foreign Powers." This represents, we may presume, the Horse Guards or military view; but the medical officers regard the matter from another and totally different standpoint. They allege that the only thing which confers any authority, power, or standing in the army is military rank, and that so long as they form part of the army and are not civilians it is necessary that they should possess it if they are to discharge their duties efficiently; that they were quite contented with "relative rank" until they were deprived of it and assured that its possession was merely nominal and valueless; while at the time when they were being dispossessed of all army rank purely military titles were being, or had already been, conferred upon all other departments and branches of the service whose functions were of a much less military nature and brought them less in contact with soldiers and army duties generally than was the case with medical officers. As regards the alleged or suggested incompatibility of military rank and title with professional zeal and merit, they regard this as a ridiculous assumption, and point to the organisation of the medical services of other nations—America and the Continent—in which medical officers possess such titles and fulfil all their professional duties with entire efficiency and satisfaction; and they add that, while it is easy to indulge in abstract notions of this sort, it is quite another thing to support them by facts. If there is a residuum of medical officers who yearn to be thought military and nothing more, and strive to conceal their medical titles, their conduct in this respect has no sympathy or support from right-minded men. The foregoing, as far as we can gather, is shortly the view entertained by the majority of

medical officers, and it is but right that it should also be represented and considered when statements like those under review are being put forward.

THE ARMY MEDICAL STAFF AND INDIAN MEDICAL SERVICE: THE ENTRANCE EXAMINATION.

It is announced that in future candidates for the Army Medical Staff and Indian Medical Service will be required to make one-half of the total obtainable marks of the examination to qualify for admission into the Army Medical School, Netley, as well as one-third of the marks in the compulsory subjects of the examination. We understand that this new rule has been introduced in consequence of a falling-off in the quality of the candidates competing, and that on representations which have been made to them the Secretaries of State for War and for India have been pleased to introduce it. This regulation has, doubtless, been decided upon in the hope of obtaining better professional men for the services, but we cannot help feeling that it will not have the desired effect, and that the responsible authorities would have done better had they sought to attract better men to the services by rectifying some of the terms of service which now press heavily on the medical officer, foremost among which are the, in some ways, unsatisfactory conditions under which the officers of the Medical Staff are serving both at home and in India. We refer especially to the question of the unsatisfactory rates of pay which the junior ranks of both services are now drawing while serving in our Eastern Empire. We understand that the total obtainable marks at the London examination are 4600. Four thousand of these are awarded for the compulsory and 600 for the voluntary subjects of the examination. Referring to our past issues we find that since the appointment of the new board of examiners in 1893 five examinations have been held. At these examinations 60 men have qualified for admission as surgeons-on-probation for the Army Medical Staff, and 73 as surgeons-on-probation for the Indian Medical Service. Had these candidates been examined under the regulation now announced only 70 per cent. of the candidates for the Army Medical Staff would have qualified and 83 per cent. of the candidates for the Indian Service. We notice that since the appointment of the new board of examiners the marking has been on a lower scale than it was in old days, and we feel that this new rule may have far-reaching effects unless it be modified. Either the number of candidates who are considered to have qualified at the next examination will be a very limited one or the examiners will be obliged to be more liberal in the view they take of the candidates' answers, which will, of course, stultify the hoped-for result. The quality of the candidates competing is, of course, regulated by the advantages and the inducements which the services offer, and cannot in our estimation be altered by any rule passed by the authorities to raise the average number of marks to be gained by the candidates at the examinations.

THE COMMANDER-IN-CHIEF.

The subject of the appointment of Commander-in-Chief in connexion with the recommendations of the Hartington Commission has attracted much attention of late, and Mr. Campbell-Bannerman's reply to a question in the House of Commons on the subject last week received different interpretations. By many it was thought that when the present Commander-in-Chief retires his successor will be appointed for five years only and not permanently, whereas others were of opinion that the post itself will be altogether abolished. Mr. A. Morton returned to the subject this week, and in reply the War Minister said that it was not usual to decide such questions until the occasion for the decision arose. When it did he had no doubt that the Government of the day would consider the recommendations of the Hartington Commission. As regarded his own views they were embodied in a separate memorandum appended to the report of the Commission, and he had since seen no reason to alter them. Mr. Campbell-Bannerman did not concur, it will be remembered, in the proposal of the Commission to abolish the appointment of Commander-in-Chief, and was opposed to the creation of a Chief of the Staff as unnecessary and likely to prove disadvantageous rather than otherwise to the service. The Medical Department, like all the other branches of the service, is more or less interested in this question, for the head of the army shapes more or less its policy. That the Duke of Cambridge has attained a good age, and that he has retained the highest position in

the army much beyond the age at which officers of high rank with plenty of physical and mental vigour have been compulsorily retired, cannot be denied. One thing seems pretty clear, however—viz., that the present Commander-in-Chief has no intention of retiring.

ENTERIC FEVER IN THE ARMY.

We have so frequently referred to the prevalence and mortality of typhoid fever in the army, especially in that portion of it serving in India, in connexion with water-supply and filters, that we fear our readers must be weary of the subject; but it is one of extreme importance, and nothing should be neglected which seems likely to prevent or lessen the prevalence of this disease. There does not seem to be any doubt that the introduction of the Pasteur-Chamberland filter in the French army has been followed by a remarkable diminution in the amount of typhoid fever. The last report of the French Minister of War furnishes some very interesting and instructive information in this respect, which is altogether corroborative of the previous reports of M. de Freycinet on the same subject. It shows that there has been a progressive decrease in the amount of typhoid fever of late years owing to the extended use of these filters. The barrack filters in ordinary use in India are, as we have often said, worse than useless as regards the prevention of water-borne diseases, and no time should be lost, we think, in giving some trial on a large scale to the kind of filter that is used at present in the French army.

THE CASE OF SURGEON-MAJOR GARDNER.

With reference to the case of Surgeon-Major Gardner M.B., Army Medical Staff, who joined the service in 1894 and resigned his commission under exceptionally pressing circumstances in October, 1890, we understand that the War Office have decided to offer no opposition to his claim for reinstatement in Her Majesty's army, and that the motion for a reconsideration of the circumstances attending his resignation, which will be brought forward by Mr. Brynmor Jones when the Army Estimates are reached, will be supported by a number of members on both sides of the House.

INDIAN MEDICAL SERVICE EXAMINATION.

An examination for not less than twelve appointments to Her Majesty's Indian Medical Service will be held in London during the month of August next. It is notified that at this and future examinations no candidate will be considered eligible unless, in addition to obtaining at least one-third of the marks obtainable in each compulsory subject, he shall obtain one-half the aggregate marks for all the compulsory subjects. The exact date of the examination will be announced subsequently.

SMALL-POX IN CALCUTTA.

It would seem that the epidemic of small-pox which has been raging at Calcutta shows some signs of abatement. According to the Indian mails the number of patients at the Campbell Hospital has fallen to 148, forty-five of whom are Europeans.

The annual dinner of the Volunteer Medical Staff of Liverpool and district was held at the Exchange Station Hotel on Wednesday evening, the 24th ult., Brigade-Surgeon-Lieutenant-Colonel Wills, V.D., being in the chair. Amongst those present were Colonel Stache, R.E., Captain Crofton, R.N., Brigade-Surgeon-Colonel Nicholson, A.M.D., Fleet-Surgeon White, C.B., Lieutenant-Colonel Hart, R.E., Major Thompson, R.E., and the President, Medical Institution.

The *Times of India* states: "Until further orders the Government of India have ruled that no Military Medical Officer will be allowed to proceed on leave unless on medical certificate. This ruling will take effect after May 15th."

Nine invalids left Ceylon in the *Jumna* for Netley on April 1st, and twenty-five invalids were notified as leaving South Africa for Netley on April 6th.

H.M. troopship *Malabar*, which left Bombay on April 4th, is expected to arrive at Portsmouth on May 3rd with eighty-three patients for Netley.

It has been decided by the Government of India to allow officers embarking direct from Rangoon for Europe Rs. 575 as passage money.

Correspondence.

"Audi alteram partem."

"MEDICAL EVIDENCE AT INQUESTS."

To the Editors of THE LANCET.

SIRS,—My attention has been called to an article in THE LANCET of Feb. 2nd referring to an inquest held by me on one James Powell, who shot himself through the head on Jan. 11th. The article is erroneous and I think you should not have inserted it in a valuable and important paper like yours without ascertaining whether it was true. It proves the folly of accepting as correct the statements of interested informants. In this case the medical man who had attended the deceased for many years was called in and arrived shortly after death, when he examined the wound, and his evidence as to its description and other matters was given at the inquest, and was satisfactory to the jury, myself, and the solicitor who represented the family. There was no need to cause unnecessary expense to the ratepayers by calling the other medical man at the inquest, who could only corroborate the description of the wound, whereas the one who gave evidence knew the deceased so well, and assisted the court in deciding as to the state of his mind, which was important in a case of this sort.

I am, Sirs, yours faithfully,

H. MILLIGAN,
Deputy Coroner.

Victoria-buildings, King-street, Wigan, Feb. 22nd, 1895.

*** We willingly insert the above and regret the delay which has occurred in its publication owing to Mr. Milligan's letter having been mislaid. We still think, however, that it would have been advisable to take the evidence of the medical man who first saw the wound.—ED. L.

ISOLATION AFTER DIPHTHERIA.

To the Editors of THE LANCET.

SIRS,—Would you allow me to express a word of warning as to the risk of accepting the absence of specific bacilli (even after expert bacteriological examination) as conclusive evidence that a suspicious case of throat affection is not diphtheria? A case of undoubted diphtheria was recently notified to me. There had been no previous case in the house or vicinity, and careful inquiry failed to obtain evidence of any probable source of infection, and the patient, having recently suffered from whooping-cough, had not been out of the house for a period far exceeding the outside period of the incubation of diphtheria, but had developed the first symptoms of that disease three days after coming in contact with her brother, who had just returned from London. His recent history was as follows. He is employed in a house of business in London, and whilst there developed a throat affection and was seen by a medical man on behalf of his employers. This gentleman considered the case suspicious and called in a second opinion, and the result of the consultation was that the patient was notified as suffering from diphtheria and forthwith removed in the ambulance to one of the metropolitan isolation hospitals, where he was injected with antitoxin. This was on March 28th, and on April 11th the patient was discharged and sent home by rail. As this was the day preceding Good Friday the train was crowded with holiday-seekers. I have communicated with the hospital authorities, and learn that this step was taken after a bacteriological examination had given negative results as regards the specific bacilli of diphtheria. In conclusion, may I be allowed to state that, on the results of etiological investigation of a very large number of outbreaks of diphtheria extending over a number of years, I have arrived at a decided opinion that in none of our ordinary severe infectious diseases are we so likely to meet with cases of prolonged infection and in none is it so important to advise the longest period of isolation practicable and reasonable? I am, Sirs, yours truly,

Shropshire, April 29th, 1895.

W. N. THURFIELD, M.D.,
County Health Officer.

"PROVISION FOR YOUNG IMBECILES."

To the Editors of THE LANCET.

SIRS,—I should like to add my support to the opinions expressed on this subject by Dr. Shuttleworth and Miss Twining. During the time that I was at the Darenth Schools for Imbecile Children I repeatedly had to refuse admission to imbecile children in various parts of England because the parents did not live in London, residence in the metropolis being necessary to secure reception of their children. Since leaving the schools, and more especially since my connexion with a London hospital for nervous diseases, I have come into contact with a large number of cases whose parents or medical attendants wished them to be admitted into an institution in order that the children might be suitably educated and trained, but I have been obliged in too many cases to say that no accommodation could be found. There is no doubt that there are very many imbecile children scattered throughout the country for whom training schools should be provided, and my opinion on this point is strengthened on reading the return recently made by order of Sir Walter Foster as to the number of imbecile and epileptic children under sixteen years of age in each workhouse, separate infirmary, school, or other similar establishment belonging to the guardians of unions in England and Wales (excluding the metropolis). It is a lamentable fact that England—which is foremost in charitable and philanthropic enterprise—lags so far behind other countries in its provision for these unfortunate children. Our American cousins are usually wide awake and not disposed to throw away their money, and yet in America there are fifteen or sixteen institutions for providing education and training, while we in England are content with six. Plenty of money is spent year by year in building asylums for the insane or adding to the accommodation already existing, and yet hardly anything is done for the training of these children. To allow the educable cases to remain in unions, where no provision for teaching is made, is a bad and expensive policy. This fact requires to be brought home to the minds of guardians and others whose business it is to look after these children, and it should be demonstrated to them that it is quite as necessary and important to make provision for juvenile imbeciles as for the insane.

I am, Sirs, yours faithfully,

FLETCHER BEACH,

Formerly Medical Superintendent of the Darenth Schools for Imbecile Children.

Kingston-hill, S.W., April 29th, 1895.

"THE WOMEN'S FREE HOSPITAL, SOUTHAMPTON."

To the Editors of THE LANCET.

SIRS,—The letter in THE LANCET of to-day from the Medical Society requires a few words of reply, and for many reasons it is fitting they should come from me. It must first of all be noticed by everyone who has carefully read the letters of this society that the charges they have formulated against the hospital and its officers have undergone frequent changes, the most notable of which occurs in Paragraph I, in which the words used up to the present, "appalling frequency," degenerate into "unusual frequency." This is most satisfactory, and I am glad the society has seen fit to alter its verbiage. I do not know even now that the words "unusual frequency" are entirely fitting when the facts are considered. When I began first to know Southampton intimately from residence in its neighbourhood I was asked to see a number of patients in consultation and to do a number of operations. I was not surprised to find a large proportion of cases of bad pyosalpinx, for Southampton is just the kind of place where I should have expected to find them. But I was surprised to find that no effort whatever had been made effectually to treat these cases as they must be treated, and I could not discover that any ever had been so treated at the Royal South Hants Infirmary. I urged the establishment of a special hospital first on Mr. J. F. Bullar, who had been one of my post-graduate pupils, and then upon Mr. Elliot. The former gentleman elected to follow another special line of practice by opening an ophthalmic hospital. Mr. Elliot followed my advice, and I took no small pains to do all I could to help him towards success, and I am glad to feel that I have succeeded. I operated on a large number of cases, some in

Southampton, many more in Birmingham. If all these had been included in Mr. Elliot's list their number in *ratio* might have, indeed, seemed to be "appalling," but they were merely the accumulation of the neglect of years. I attended meetings of the Southampton Medical Society, I showed specimens of Fallopian bags of pus fresh from Southampton patients, I did my best to instruct my audience in the diagnosis and treatment of such cases—some if not the whole of the surgical staff of the infirmary were present—but up to the present day it would seem as if gonorrhoea and its products were unknown in Southampton so far as the infirmary is concerned, for not a case of damaged appendages is yet recorded as having been dealt with there. There may be, yet I know that in spite of all my warnings and preaching against what has most erroneously been termed "Tait's operation" there has been a removal of uterine appendages far too widely extended. Hardly a month of my life passes in which I have not at least once to interfere and prevent an operation being performed, and it is very likely that I have given my vote against proposals of the kind at Southampton. This has happened in a number of cases at Southampton, and this fact goes to prove not only that I exercised the repressive influence which all consultants similarly placed must occasionally be called upon to exercise, but that Mr. Elliot loyally abided by my advice. Some of these cases the members of the Southampton Society have hunted up, and they pervert, or wish to pervert, the legitimate inference to be drawn from them. That early experience will conclude for the necessity of operation and that maturer experience will decide against it is the fact of most striking importance in the whole history of such operations as strabismus, excision of joints, &c. If it were not so, what would be the good of extending experience? There may be yet, as there have been, errors of commission; but are those who deliberately and persistently sin by omission to have no word raised against them? I assert that the greatest possible care has been used in the practice of the Women's Hospital at Southampton to avoid errors of commission, and the fact that the Medical Society of Southampton decline to hear the details of all the cases performed there read before them and be themselves the judges shows that they know this to be true. However, such a paper will be read before the British Gynecological Society, and then I challenge the members of the Southampton Medical Society to produce any evidence they may have to the contrary.

One word as to the resignation of "four non-resident members of the society" arising directly from this issue. From the lightsome way in which this resignation is spoken of your readers might be led to regard it as of no consequence. They are "non-resident" members in the sense that they do not dwell within the borough of Southampton, but they were the four most distinguished members of the society, four members of the staff of the neighbouring Government Medical School at Netley, quite closely enough resident to know all the facts—men of position and knowledge to be able to judge correctly, so completely free from local prejudice as to give an unbiased judgment and to satisfy themselves of the real basis of all the complaints.

I am, Sirs, yours truly,

Birmingham, April 27th, 1895.

LAWSON TAIT.

To the Editors of THE LANCET.

SIRS,—The committee of the Women's Hospital are at one with the Medical Society in the determination, as expressed in their last letter, to avoid a newspaper correspondence, and this communication is the last they will make on the subject at issue.

They emphatically decline, as in the beginning, to recognise the claim of the Medical Society to interfere in the affairs of the hospital, holding as they do the opinion that its action has arisen only from a "mean and despicable jealousy," utterly apart from any true regard for the interests of the profession or for the welfare of the sick—a fact now thoroughly appreciated in Southampton. If complaints had reached them in any legitimate manner, such as from patients (or their friends) who had been treated in the hospital, or from subscribers to the charity, or from leading members of the profession, unbiased by local influences, they would have at once removed any defects brought to notice; but not a single complaint from any one of these sources has been made. The committee, therefore, resting their case on the integrity of their actions and on the weight

of evidence that has accumulated since this correspondence commenced as to the value of the work done at the hospital, may justly ignore the attempts to injure it so persistently and unworthily made by the Medical Society.

We are, Sirs, yours faithfully,
A. F. FORBES, M.A., Chairman.
H. C. PHILLIPS, Hon. Sec.

Southampton, April 30th, 1895.

To the Editors of THE LANCET.

SIRS.—The committee of the Women's Hospital regret that Dr. Playfair should have made any mistake as to the correspondence they referred to. The committee referred to the following correspondence which took place in November, 1894:—

[COPY.]

"SOUTHAMPTON MEDICAL SOCIETY.

"Hamilton House, Southampton.
"Nov. 21st, 1894.

"DEAR SIR,—I am instructed by the committee of the above society to forward you the enclosed copy of a letter from Dr. Playfair, consulting physician to the Women's Free Hospital, Southampton, which has been sent to Dr. Gwillim, joint hon. sec., Southampton Medical Society. Will you kindly lay it before your committee? I am instructed also to request the favour of an answer to the circular which was sent last week to your committee.

"The committee of the Southampton Medical Society think that they may reasonably expect an answer within a fortnight, and if none is received within that time they will feel justified, considering the gravity of the matter involved, in taking such further action in the matter as they may deem expedient.

"I remain, yours faithfully,

(Signed) "NORMAN ALDRIDGE,

"Joint hon. sec. Southampton Medical Society.

"H. C. PHILLIPS, Esq.,

"Hon. Sec. Southampton Free Hospital for Women."

[COPY.]

"31, George-street, Hanover-square, W.,
"Nov. 18th, 1894.

"DEAR SIR,—I have been asked by Dr. Bullar whether in my opinion the questions put to the committee of the Women's Free Hospital in Southampton, in your circular of Nov. 8th, are such as are reasonable, and should receive a full and explicit answer. To this I have no hesitation in replying fully in the affirmative. In my opinion when any question arises as regards the working and results of such an institution in its own interests the more fully details are given the better. Personally I know nothing of the Southampton Free Hospital for Women. When I was asked to become consulting physician I consented under the full belief that it was all that such a hospital should be.

"Now that this has been called in question I am distinctly of opinion that its committee should afford every facility for a full and ample investigation of its working and results.—I am, faithfully yours,
(Signed) "W. S. PLAYFAIR."

As Dr. Playfair corresponded with the Medical Society some weeks before he wrote to his committee the committee naturally treated his latter communication in the only manner which was open to me. The committee do not think they need repeat their views on this subject, but would like to point out that they never attached the word "dis-courteous" to Dr. Playfair's correspondence, but to the manner in which he has treated them.

We are, Sirs, yours faithfully,
A. F. FORBES, M.A., Chairman.
H. C. PHILLIPS, Hon. Sec.

Southampton, April 30th, 1895.

REGISTRATION OF MIDWIVES.

To the Editors of THE LANCET.

DEAR SIRS,—Kindly oblige the guardians by publishing the enclosed.—Your obedient servant,

JNO. H. RUTHERGLEN, Clerk.

[COPY.]

"ST. MARY ABBOT'S, KENSINGTON.

"Guardians' Offices, Marlborough-road, Kensington, W.,
"April 30th, 1895.

"SIR,—The guardians of this parish, who for some years past have trained in the special lying-in wards attached to their infirmary a large number of trained nurses to pass the examination of the London Obstetrical Society, have heard with much regret of the resolution passed by the General Medical Council on Dec. 3rd last with respect to the issue of midwifery diplomas or certificates in general, and of the certificates of the Obstetrical Society of London in particular. The guardians are the more surprised at this action as they have always understood that the General Medical Council have regarded the absence of public provision for the education and supervision of midwives as being productive of a large amount of suffering and disease among the poorer classes, and that the Council had been recommended by a Select Committee of the House of Commons to frame rules for the conduct of examinations for the admission of women to act as trained and certificated midwives. It was to a great extent to meet these expressions of opinion that the guardians of this parish undertook, in conjunction with the Workhouse Infirmary Nursing Association, the yearly training

of a number of previously qualified nurses in their midwifery wards, but they have every reason to fear that if the resolution of the Council stands, and the London Obstetrical Society therefore ceases to issue in its present form its diploma or certificate of competency, the good work which they have been doing for so many years will cease, as women will be unwilling to enter for a course of training for which they will be unable to obtain a certificate of efficiency, qualifying them to act as midwives. Having regard, therefore, to the value and importance which is attached to special training in midwifery, and to the examinations conducted by the London Obstetrical Society and other bodies, the guardians have directed me to ask that the General Medical Council will reconsider and withdraw their resolution of December last, so that the training and sending out of competent midwives may be continued unimpeded.

"I am, Sir, your obedient servant,

"JNO. H. RUTHERGLEN, Clerk.

"The Registrar, General Medical Council,
"239, Oxford-street, W."

"DEGREES OF KNEE-JERK."

To the Editors of THE LANCET.

SIRS,—Will you kindly give me a few lines of your space to make a slight addition to an article under the above title in THE LANCET of March 30th, 1895? In the last sentence but one, on p. 802, I expressed a hope that someone would invent an instrument which should enable us to measure the degree of any given jerk. My attention has been drawn to an article by Dr. Ewen Maclean in the *Bristol Medical-Chirurgical Journal* for March, 1892, in which he describes and figures such an instrument; he calls it a "jactometer," and it was made for him by Messrs. Down Bros., of London. His instrument fulfils so completely the three requirements I mentioned in my article that I think I must have heard or read of his invention before I wrote the article. If so, I had quite forgotten all about it, and I know I had not read his paper when my article appeared. I have not yet had an opportunity of seeing it in working, but I hope that all who are interested in the knee-jerk will read his paper and if possible try his instrument. It appears to me to be very ingeniously constructed.

I am, Sirs, yours faithfully,

London, April 30th, 1895.

LEONARD J. KIDD.

"A CASE OF EQUINIA (GLANDERS); RECOVERY."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 16th Mr. T. W. H. Garstang records, under the above heading, a supposed case of glanders in a veterinary surgeon. The patient was thought to have contracted the disease while treating a horse affected with "nasal catarrh of a suspicious type," but, strange to say, both man and horse ultimately recovered. It appears to me that this fact throws grave doubts on the accuracy of the diagnosis in both cases. It is admitted that recovery from glanders is exceedingly rare in man, and in the horse it is essentially a fatal disease. I am not aware that there is any recorded case of recovery from glanders. Owing to the difficulties of making an accurate diagnosis in certain cases in the horse, cases of "nasal gleet" have in times past been mistaken for the specific disease, and on their recovery it has been claimed that they were genuine cases of glanders, but I do not think any authentic case of glanders has ever been known to recover. It is not for me to question the accuracy of Mr. Garstang's diagnosis in his case, but I should like to make a few observations on the opinions expressed by his patient on the subject of glanders in the horse. I have no means of knowing who the veterinary surgeon is, or whether he is a member of the Royal College of Veterinary Surgeons, or only a registered practitioner without any qualification, but it seems evident, from the statement attributed to him in Mr. Garstang's article, that he has not kept himself acquainted with the latest knowledge on the important question of glanders. He is reported to have said "that glanders always commences with nasal gleet, from which the animal may recover; but that when the gleet runs on to glanders or farcy recovery is impossible." In this statement appears the confusion I have referred to above. Chronic nasal catarrh or nasal gleet cannot run on to glanders. It is a non-specific disease affecting the mucous membrane lining the nasal passages and sinuses. It is often very difficult to treat, and usually proved most obstinate, but recovery may and frequently does take place. There can be no connexion between the local affection known as nasal gleet and the fatal specific disease glanders. Glanders begins with a discharge from the nasal passages, followed by other symptoms specially characteristic of the disease—ulceration

of the Schneiderian membrane, enlargement of the lymphatic glands &c.—but it is a specific disease from its commencement and runs a regular course invariably ending in death. Unfortunately the nasal discharge in glanders may for a long time be unaccompanied by any other visible sign of the disease, and it is in these cases that we find the greatest difficulty in deciding whether we have to deal with a simple nasal catarrh or with the dangerous malady glanders.

A few years ago, the only means of deciding whether such a discharge was specific or not was by inoculating a donkey with the discharge and waiting the result. If the case was glanders, then the donkey became affected, and all doubts were ended. To-day we have another aid to diagnosis in mallein, which is used as an inoculation in a suspicious case, and which produces certain definite results whenever glanders exists. It is reliable, and by its use we can detect latent cases of glanders, even where no discharge or other symptom has been noted. Then the veterinary surgeon goes on to say "that a horse suffering from nasal gleet may infect healthy horses with glanders or farcy, and yet may not show any symptom beyond the gleet, and may eventually recover, while the horses infected by him will die of the disease." Here is another fallacy. If the horse with the nasal discharge has glanders of course he may communicate the disease to other horses in close contact with himself and they may die while he may *apparently* recover for a time; but the improvement is only temporary and sooner or later acute glanders will supervene, rapidly ending in death. If, on the other hand, the horse is merely suffering from chronic nasal catarrh he cannot infect other horses with glanders, and if the other horses do become affected with glanders we should have to look for another source of infection. If the horse which was thought to have communicated glanders to the veterinary surgeon was only suffering from nasal gleet, he probably would recover as stated, but he could not produce glanders in the man. If he *was* suffering from glanders and appeared to recover, then sooner or later the disease will become acute and will cause his death.

I cannot believe in a case of simple nasal gleet running on to glanders or farcy, nor in true glanders ending in complete recovery. It is much to be regretted that the case in the horse was not tested by an inoculation of mallein, which would have set all doubts at rest. I do not know whether the mallein test has ever been tried in the human subject, but it seems worthy of trial, and might have been useful in the case recorded by Mr. Garstang. It would be most interesting to hear something of the later history of the horse in question, whether his recovery has been permanent, or whether any relapse has occurred. If the horse has *completely* recovered, as stated, I should say positively that he has never suffered from glanders, and that if Mr. Garstang's diagnosis was correct he must look for another source of infection. If the horse is still alive it would be most interesting to learn whether an inoculation of mallein would produce any effect. It would decide positively whether he has glanders or not, for it is possible for a horse to suffer from chronic glanders for many months before the malady becomes acute, the disease being confined to the lungs and producing no visible sign of ill-health. At any rate it is impossible for a veterinary surgeon to accept the statement that the horse has had glanders, has conveyed the disease to a man, and has completely recovered. With many apologies for taking up so much space,—I am, Sirs, yours faithfully,

T. W. CAVE, M.R.C.V.S., F.R.M.S.

University College, Nottingham, April 22nd, 1895.

THE DISCOVERY OF ANÆSTHESIA.

To the Editors of THE LANCET.

SIRS,—It seems to me that Dr. Preston's letter in THE LANCET of April 20th, claiming the discovery of anæsthesia for Dr. Long, ought not to go unanswered. Some ten years ago I investigated this most interesting, but highly complicated and little known subject, and the conclusions at which I arrived were as follows. Priestley¹ discovered nitrous oxide gas in 1772. In 1800 Sir Humphrey Davy² discovered its anæsthetic properties and successfully inhaled it himself to relieve the pain of cutting a wisdom

tooth. In his account of these experiments there occurred this memorable sentence: "As nitrous oxide in its extensive operation appears capable of destroying physical pain, it may probably be used with advantage during surgical operations in which no great effusion of blood takes place." Strange to relate, nothing came of these remarkable observations. Their real import was not understood until nearly half a century later. One winter's night in December, 1844, a number of the inhabitants of Hartford, U.S., assembled to hear a lecture on nitrous oxide and other gases from Dr. Colton, a well-known popular lecturer, who tried the effect of the first-named gas on several of the audience. Among those present was Dr. Horace Wells, a dentist of that city. He noticed that a person under its influence sustained a severe injury of his leg without feeling any pain. Wells was so impressed with this fact that the next day he got the lecturer to give him the gas, and while under its influence he had a molar tooth extracted without feeling the least pain. As he recovered from the effects of the gas his first words were: "A new era in tooth-pulling."³ The modern practice of anæsthesia dates from this operation. He soon afterwards gave the gas to more than a dozen of his patients, and with complete success. There can be no doubt that Wells, as indicated by the title of his pamphlet, "The History of the Discovery of the Application of Nitrous Oxide Gas, Ether, and other Vapours in Surgical Operations," had thoroughly grasped the anæsthetic idea, which in its subsequent developments so completely revolutionised surgery. He alone, in my opinion, is entitled to be regarded as the discoverer of modern anæsthesia. After his tragic death in 1848 his discovery was again in danger of being lost. Colton's praiseworthy endeavours to reintroduce it were in vain until 1863, when he succeeded in getting a few practitioners to try it. Subsequently its use spread rapidly. Among those present at Wells' ill-fated trial of gas at the Boston Hospital was his former pupil, Dr. Morton, and Dr. Jackson, lecturer on chemistry. Desiring in 1846 to use the gas in dentistry Morton applied to Wells for instructions how to make it. Wells referred him to Jackson, as the latter was a scientific man and a chemist. Jackson advised Morton to use ether instead, as it possessed the same properties and was as safe and easier to get.⁴ Acting on Jackson's suggestion, on Sept. 30th, 1846, Morton painlessly extracted a bicuspid tooth from a man named Eben Frost. Thus the anæsthetic properties of ether were first practically demonstrated. In the following October several important operations under its influence were performed at the Boston Hospital, Morton being the administrator. In a wonderfully short time ether was in use nearly all over the civilised world. Probably no great improvement in the practice of medicine, once started, ever became so rapidly established. This was no doubt in a measure due to the fact that prior to Morton's discovery the properties of ether were not altogether unknown. It had often been inhaled both in America and elsewhere as an excitant. In 1818 Faraday had pointed out that the effects of inhaling its vapour were similar to those produced by nitrous oxide gas, and it was subsequently customary in the college courses both in Europe and America to illustrate this fact by various experiments. The resemblance between the action of nitrous oxide and ether vapour was therefore well known. A French dentist, Parmentier of Paris, had occasionally anæsthetised his patients with ether prior to 1840. Dr. Wilhite, of Anderson, U.S., accidentally anæsthetised a patient with ether in 1841. We next come to Dr. Long, an English physician practising in Jefferson, U.S., who in 1842 performed a surgical operation on a patient thus anæsthetised. As, however, none of these persons published any account of their experience, the far-reaching importance of which they failed to discover, it is impossible to accord to any of them the honour of the discovery, for in a matter of this sort publicity is the touchstone of invention. Such are the isolated antecedent facts subsequently brought to light after the practice of ether inhalation had been established by Morton, to whom, in my opinion, the chief credit is due, for the history of all great discoveries shows them to have cast similar shadows before.

I am, Sirs, yours truly,

Preston, April 25th, 1895.

"MEDICAL SOCIETIES AND HOMŒOPATHS."

To the Editors of THE LANCET.

SIRS,—I read your leading article on the above subject in THE LANCET for April 13th, but did not know that you expected or would admit a reply to your "arguments" until I saw in to-day's issue that you apparently expected such a reply. As I happen to be a member of the Pathological Society of London of more than forty years' standing, I suppose I may consider your article includes a reference to my membership in this society. I may say that I joined this society in order to keep myself *au courant* with the progress of pathological knowledge, and not with any view of enlightening its members on any peculiar pathological theories or doctrines held by the school of homœopathy, for I may add that our school has no peculiar pathological theories or doctrines, and that the pathology we profess is precisely that taught in the ordinary medical schools. Such being the case, I do not see how my peculiar therapeutic views should disqualify me from being a member of a pathological society which is of no therapeutical faith. I do not happen to be a member of any society of general medicine which has to do with therapeutics, the homœopath societies proper being quite sufficient for my wants. But as according to the confessions of your most eminent men the therapeutics of the non-homœopaths are in a most imperfect and unsatisfactory state, I do not think it would do the general profession any harm, but probably much good, if they had in their societies members who are conversant with the reformed therapeutics of homœopathy. As we observe with amusement the frequent recommendations in THE LANCET and other medical periodicals, as newly-discovered remedies, of medicines that have long been used in our school, and for precisely the same affections as they are employed in homœopathy, it might on the whole be better that you should obtain a knowledge of these medicines and their therapeutic uses at first hand, from those who have long employed them, than have them introduced into your practice in the indirect and roundabout manner they are at present. To object to us as "irregular practitioners" seems to me to be very absurd, as we are the only medical men who really practise according to a *regula* or rule, and eminent authorities in your school have declared that medicine as they practise it has no principles, and that their treatment is not guided by any rule. I can assure you that those whom you call "homœopaths" are not, as a rule, desirous of joining your therapeutic societies, as they know they would meet with but scant courtesy from the members; nor are we at all desirous of having consultations on medical treatment with adherents of the old school, as we think that our own therapeutic method is infinitely superior to yours, as we are always ready to prove by reasoning and by results.

I am, Sirs, your obedient servant,

R. E. DUDGEON, M.D.,

Member of the Pathological Society, and Consulting Physician to the London Homœopathic Hospital.
Montagu-square, April 27th, 1895.

To the Editors of THE LANCET.

SIRS,—On page 1094 of the current number of THE LANCET you say: "If this is the only answer homœopaths can give to our arguments, further remarks on the subject would seem not to be called for." The inference is that if homœopaths have anything further to say you are willing to place it before your readers. I will therefore avail myself of your courtesy and offer a few brief remarks on the subject of your leading article in THE LANCET of April 13th on "Medical Societies and Homœopaths." Allowing for the moment that homœopathy is a delusion, and agreeing fully with your own view that this delusion, however unfortunate it may be, refers only to "the limited department of drug treatment," it is not obvious to those who view the matter from a standpoint other than your own that there is left no common ground between the "homœopath and the general body of the profession." Consequently to refuse to meet "homœopaths" either in "consultation upon an individual case" or at a medical society "in a conference upon any question of scientific interest" appears irrational and illiberal. In these days superstitions die an easy death when once the light of science is allowed fully to shine in upon them. No scientific society has ever investigated the pretensions of homœopathy except such societies as were composed of

medical men already ostracised for having investigated them. To permit its claims to be thoroughly sifted in the light of day would result, if they are fallacious, in their final repudiation in a far shorter time than by any other method. The ever-changing measures and methods of modern therapeutics suggest that some enduring guide to the administration of drugs is at least a *desideratum*. It is claimed by thousands of educated practitioners and teachers of medicine that homœopathy affords such a guide. That it is "partially true" is acknowledged by authorities so high as Lauder Brunton and Sidney Ringer. This being so, the leaders of the general body of the profession are incurring a serious responsibility in declining to investigate a method so promising. That "homœopathy in the strict sense" is extensively practised in this and other countries is a fact of which you appear to be ignorant. That it is in some instances a safe and useful guide to treatment is easy to prove from writings the soundness of which even you yourselves would not question. Just how far it may be trusted is a point which demands a patient and vigorous investigation at the hands of those competent, by education and open-mindedness, to decide. The resources of the learned societies are required for this noble and pressing purpose. A few years devoted to the subject by those possessed of brains and money would suffice to settle the question, to advance therapeutics from a changing art to a stable if juvenile science, and to remove the disgrace of medical schism.

I am, Sirs, yours truly,

London, April 29th, 1895.

EDWIN A. NEATBY, M.D.

"HOSPITAL PATIENTS AND IMMORALITY."

To the Editors of THE LANCET.

SIRS,—In reference to the annotation "Hospital Patients and Immorality" in your last issue, with the tenour of which I most fully and heartily concur, permit me to point out that your annotator has been led into error as to the statements attributed to me through trusting to a Sunday contemporary which contained an altogether insufficient and totally unauthorised account of my remarks. The meeting at which I presided was addressed by the Rev. the Marquis of Normanby on the subject of "Temptation and Self-control," with especial reference to impurity. In my chairman's address, after alluding to the importance of the subject and illustrating the need of self-control in the ordinary affairs of physical and social life, one turned to the many forms of want of control which young men were especially prone to develop, prominent among them being impurity, intemperance, gambling, and other such vices, which left their marks not only on the moral but also on the physical nature of those who indulged in them, adding by way of emphasis the statement to which umbrage has been taken, but which referred not only to the results of impurity but also to the other excesses to which I had already alluded. To such a statement surely no one can take exception. Moreover, as to statistics, I was most definite in pointing out that none were to hand, and hence my estimate was to be taken with a certain amount of reserve, rather as an impression received from many years of hospital work than as an accurate statement of facts. Under these circumstances I think you will agree with me that the want of accuracy lies not with the most carefully guarded remarks made by myself, but in the incorrect interpretations which have been placed upon them by others and in the want of care evidenced by those who copied such a statement without verifying it.

I am, Sirs, yours obediently,

Welbeck-street, W., April 30th, 1895.

ALBERT CARLESS.

"THE NECESSITY FOR A CENTRAL MEDICAL ORGANISATION."

To the Editors of THE LANCET.

SIRS,—When reading my paper on "The Necessity for a Central Medical Organisation" before the Hunterian Society on Wednesday last the time at my disposal did not allow of more than a very brief sketch of the organisation I proposed. It was, I think, generally agreed that an organisation is necessary and that there is no organisation at present which meets the necessities of the profession. As there was a slight misunderstanding about the scheme I suggested

will you allow me to give it a little more in detail? I suggested a coöperative association which embodied the following idea. It consisted, in the first place, of a union of medical societies, whose members supplied the funds—either as shares or as subscriptions guaranteed for a number of years, preferably the former, which are essential, in my opinion, to the success of any undertaking of this nature or with this object. The local organisation of the profession would be carried out by boards in each district, and from these boards delegates would be sent to form the board of directors of the association. This board would therefore be composed of medical men in direct touch with every part of the kingdom. Through it local as well as general unity of action might very well be arrived at. The medical societies of the United Kingdom represent, on the average of the three kingdoms, about 50 per cent. of the medical profession, and might therefore be utilised for the purpose suggested. Such a coöperative association, with money at its command, would be capable of successfully meeting the many lay as well as the so-called charitable competitors we have to contend with. It could cope with the prescribing druggist, with medical aid associations, with the abuses of hospitals and public dispensaries, and with provident dispensaries and their sweating system. I will refer to the method by which it might deal with lay medical aid societies, as this point was especially animadverted upon in the discussion which followed the paper. By the transference from the lay companies to the medical coöperative association of the business of the former, the medical officers now attached by bond or by necessity to them would be freed from lay restraint and from "sweating." This could, I have every reason to believe, be accomplished by the process of underselling them or by buying them out, or by both methods combined, and without much difficulty. I cannot see that this would bring the association into conflict with the tenets of medical etiquette. Obviously, it need not affect the medical officers. One important result of such action would be that insurance societies would be very chary of embarking capital in a business when they knew that they would be systematically undersold to an extent which would cause them to fail to earn a dividend. Such an association as I have suggested would have far more power over its members than any body supported by voluntary contributions. It could unite the existing protection, insurance medical societies &c., and could afford its members exceptional facilities, as in supplying them with drugs, instruments, &c. at manufacturing or greatly reduced rates, 35 per cent. being commonly added to the cost of production. In conclusion, I shall be happy to hear from any medical men who agree with me as to the necessity for a central medical organisation, and if together we can produce a workable scheme and can start it the amount of time expended on such an object will be well repaid in feeling we have benefited our profession.

I am, Sirs, yours truly,

Fellows-road, N.W., April 27th, 1895.

F. R. HUMPHREYS.

"THE THERAPEUTICS OF PAPAIN."

To the Editors of THE LANCET.

SIRS,—Dr. Younger's article in THE LANCET of April 27th is a most interesting contribution to the therapeutic value of papain. All the cases he relates refer to a functional disturbance of the digestion, and most of them are accompanied by a condition of anæmia. It seems probable that both atonic dyspepsia and gastric ulcer, to which it stands in close relationship, are always connected, either etiologically or consequentially, with an impoverished state of the blood; there is, therefore, in both disorders an urgent demand for such blood tonics as arsenic and iron. In most cases, moreover, pain is a more or less urgent symptom, and for its relief an anodyne is often essential. Dr. Younger recognises all this because in many of his cases he administered iron, though in comparatively small quantities, while in others he resorted to the use of morphia. The papain seems on each occasion to have been ordered in an acid menstruum, and the iron administered separately. If there is great irritability of the stomach any medicinal mixture, from its disagreeable taste, is apt to produce nausea if not actual sickness, while the mineral acids are not always indicated and are sometimes very badly tolerated. In my own experience these difficulties have been overcome by the administration of the required drugs in pill form; and while each case demands a combination suited to its particular

needs it may be of general interest to state that the following formula, when combined with a suitable regimen, has again and again yielded most excellent results:—R Ferri sulph., papain (Finkler), aa gr. ij.; ext. cannab. ind., ext. nuc. vomic., aa gr. ½; ext. rhei, gr. ½; ft. pill. Sometimes reduced iron suits better than the sulphate, at others arsenic meets the requirements of the case better than nux vomica, and occasionally morphia is more efficacious than cannab. indica; but I am convinced that, apart from these necessary differences in detail, the full value can only be got from papain when it is administered in association with such other medicinal agents as the crying symptoms of each case declare to be essential, and that in a large proportion of deranged stomachs it is best tolerated in the form of a pill. I have repeatedly found the drug disappointing when given alone, but cases such as those reported by Dr. Younger, or those mentioned by myself in your issue of Feb. 9th, strongly proclaim its signal effect when administered under suitable conditions.

I am, Sirs, yours faithfully.

Warwick, April 29th, 1895.

GUTHRIE RANKIN.

"THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED."

To the Editors of THE LANCET.

SIRS,—I was very much surprised at the letter of "One Interested" in THE LANCET of April 20th, as his experience of the London and Manchester Industrial Assurance Company has been so very different from that of others who have written to you concerning it; but I am confident he would have had a different tale to tell had he kept an accurate record of the medicines supplied to his patients during the year. As it is he only "estimates" the medicines supplied; consequently neither he nor anyone else can definitely say what number of bottles was actually dispensed, and his statements in favour of the above company are in consequence open to doubt. On the other hand, I can give an accurate account of visits and medicines supplied from Sept. 29th, 1894, to March 25th last. I can also give an account from Feb. 7th, 1894, when I became referee, to Sept. 29th, 1894; but during that time I did not take note of all "repeats," consequently the numbers are much under what they would have been had I kept an accurate record. However, I prefer to let them stand as they are rather than estimate the additional numbers. They are as follows:—

	Bottles.	Visits.	Paid.
March 25th to June 24th, 1894	117*	51	£ s. d. 3 17 0
June 24th to Sept. 29th, 1894	346*	59	9 13 7
Sept. 29th to Dec. 25th, 1894	250	59	9 14 6
Dec. 25th, 1894, to March 25th, 1895 ...	222	66	9 5 0
Totals for year	935*	235*	32 10 1

* These are below the correct numbers.

That, worked out, gives only 8½d. for each bottle of medicine and leaves nothing for visits. If that is not sweating a medical man I should like to know what is. Even a "sixpenny" dispensary would pay better. These figures would have been still less favourable had I not refused during the last two quarters to treat as club patients those able to pay an ordinary fee and chronic cases, of whom there were not a few on my lists for the previous quarters. Mr. Woodward says in a letter in your issue of March 30th that the medical officers "are as well remunerated by us as by their private practice amongst the same class of people." To what class of practice does he refer? I am not aware that there is any cheaper class of practice than that carried on in "sixpenny" dispensaries, yet I have shown that his company does not pay as much.

The facts I have just stated constitute, if I may so term it, the "primary sweating" that everyone who carries out his agreement with the company has to suffer. Now let me expose the "secondary sweating," which as yet none of your correspondents has mentioned, and which seems an integral part of the system. Shortly after I had agreed to act as referee the district superintendent called upon me and told me that in order to obtain a large list it would be necessary

for me to attend patients immediately on their joining the society, and he also tried to persuade me to make a low uniform charge for each accouchement. I told him that, as far as accouchements were concerned, I should do nothing of the kind. He then remarked to a collector who was with him to the effect that they could not place on my list many *enccinte* women who might join the society and wish to be attended by one of their medical officers. As regards immediate attendance, unfortunately for a short time I agreed to it, and the result was that a number of people joined the society for a few weeks in order to get medical attendance and then left it. For those patients, of course, I got no payment whatever, as their names did not appear on the quarterly list. This, Sirs, is what I term "secondary sweating," as it is produced not by fulfilling the terms of agreement with the company, but by its agents. I should like to ask Mr. Woodward if the company approves of such actions on the part of its subordinates; and, if so, what right has the company to ask a medical referee to do more than he has agreed in writing to do? If the superintendents and agents act on their own account, the sooner they are placed under proper control the better, as I know that those who do not agree to the "secondary sweating" have very little chance of ever getting a large list from the company, which, even under the most favourable circumstances, would scarcely pay expenses. I must express my regret that I ever, through ignorance, had any connexion with such a company.

I am, Sirs, yours faithfully,

St. Peter's-park, W., April 29th, 1895.

C. W. J. DUNLOP.

"THE TITLE OF 'DOCTOR.'"

To the Editors of THE LANCET.

SIRS,—Mr. Cotton's argument is just the converse of mine. Every doctor of medicine is a physician, but every physician is *not* a doctor, is my contention. A doctorate is a university degree; the possession of a licence in medicine or surgery only makes a man a "Licentiate." The Licentiate of a College of Surgeons is undoubtedly a surgeon, and the Licentiate of a College of Physicians is undoubtedly a physician; but neither the one nor the other is a graduate in medicine or surgery, not a doctor of medicine or surgery, and not a "doctor" at all in the just and strict professional sense. Mr. Sewell remarks that I suggest "no likely remedy" for the present state of matters. The remedy is surely obvious enough; let men call themselves what they professionally are. The practice of medicine or surgery for gain is not illegal unless a title implying legal qualification is assumed—then punishment can be inflicted. On the other hand, no matter what legal qualification a man may possess he may call himself "Dr." with impunity. This I hold to be unsatisfactory, to be false representation, and misleading to the public.

I am, Sirs, yours faithfully,

Glasgow, April 27th, 1895.

D. CAMPBELL BLACK.

"MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS."

To the Editors of THE LANCET.

SIRS,—My attention has been called to an annotation in THE LANCET of April 20th under the above heading, upon which I shall be obliged if you will kindly allow me to make a few observations. In the first place I may be permitted to state that nothing can be more foreign to the intention of the Board than to put any slight upon the medical profession. With regard to the subject of your annotation it is desirable clearly to define the object of the Board in the proposed appointments, and to set forth the considerations which have influenced the Board in the matter. In February, 1893, the Board, upon the recommendation of the members of the Tower Hamlets division, decided to authorise the appointment of three medical gentlemen in that division to examine cases in which a medical certificate produced by a parent as a reason for the non-attendance at school of his child was considered to be doubtful or unsatisfactory. It had been found that parents who, for one reason or another, desired to keep their children from school frequently presented certificates which were unsatisfactory, either on

account of the vagueness of the terms employed or of a doubt as to the seriousness of the malady from which the child was alleged to be suffering. In other cases it was found advisable, for the sake of the child and of the school, to have a definite medical opinion; but delay and embarrassment arose from the absence of means available for the purpose.

I have before me a report of the Tower Hamlets divisional members upon the result of the experiment up to June, 1894. In this report, covering a period of fifteen months, the divisional members state that they consider the results, on the whole, satisfactory, and that they find that the opportunity of obtaining an independent medical examination has had a very beneficial effect in preventing idle excuses of illness and in securing the attendance of children who otherwise would probably have remained out of school. Indeed, the result of the experiment in the Tower Hamlets division has been such that members for other divisions of the metropolis are desirous of adopting a similar plan. I may here remark that the appointments in the Tower Hamlets division were made with the concurrence of the magistrates having jurisdiction in that division, and that appointments which the Board have recently decided to make in the East Lambeth division will similarly be submitted to the magistrates having jurisdiction in that division. I would beg to be allowed to point out that the medical certificates which are submitted by parents with regard to the attendance of their children at school are not, as your remarks would seem to imply, given by medical practitioners as a matter of courtesy to the Board. On the contrary, they are procured by the parent for production as evidence of the child's inability to attend school. In conclusion I would venture to remark that, so far from the question of the school attendance of a child being, as you suggest, a "trivial matter," it is, in my opinion, and I think nowadays in the opinion of most people, a matter of vital importance, not only to the future welfare of the individual child, but also indirectly to the community generally.

I am, Sirs, yours faithfully,

JAMES W. SHARP,

Chairman of the School Accommodation and Attendance Committee.

School Board for London, Victoria-embankment, W.C.,
April 30th, 1895.

COVENTRY PROVIDENT DISPENSARY.

To the Editors of THE LANCET.

SIRS,—We are glad to be able to inform you that at the annual meeting of the above institution held on Tuesday last the resolution passed in May, 1893—viz., "that the institution being now self-supporting the pecuniary position of an applicant shall be no bar to his admission"—was rescinded. The proposition that it be rescinded was made by the chairman of the committee, seconded by the vice-chairman, and carried by the meeting unanimously. This was the result of the strong representations which we, the staff of the institution, had made to the members at a meeting specially called on account of the position in which the resolution placed us. The result of this is that the institution reverts to the lines on which it has been conducted for over sixty years—viz., that it is an institution for the working classes, and that the names of all applicants for admission are submitted to the monthly meeting of the committee, who exercise their discretion in refusing or accepting them. We send you this information in order that you may be able to let your readers know that we are anxious that our institution should be conducted on principles which are recognised by authorities in our profession.

We are, Sirs, yours faithfully,

D. McVEAGH,

M. FENTON,

CHARLES DAVIDSON, M.D.,

W. J. PICKUP, M.D.,

T. A. HIRD, M.B.

April 29th, 1895.

"A PROLONGED CASE OF HICCOUGH."

To the Editors of THE LANCET.

SIRS,—In reading the report of "A Prolonged Case of Hicough," by Mr. D. Ferguson, I was very much surprised to find no mention made of ol. terebinth. being tried, the more so as he had the advantage of consulting three or four

medical friends. It is mentioned in “Fagge’s Practice of Medicine.”¹ I used it a few years ago in a case which had lasted nearly two days, and it yielded at once to a twenty-drop dose. While on the subject of therapeutics, I would like to ask whether it is desirable to administer medicines to women during menstruation. I do not, of course, allude to acute cases, but to such remedies as tonics or alteratives when continued for some time. Should they be discontinued during menstruation, and if so, why?

I am, Sirs, your obedient servant.

J. WIDMER ROLPH

Medical Officer, Pahang Corporation, Ltd.
Kuantan, Pahang, March 27th, 1895.

REVACCINATION.

To the Editors of THE LANCET.

SIRS,—Does the fee for revaccination depend upon a successful result? Small-pox has broken out in my locality, and owing to the local opposition to the Vaccination Act the neighbourhood is in a very unprotected state. The rush for revaccination is beginning, and, of course, many of the cases will prove to be already sufficiently protected, and no result will show. These, however, will require as much care, and it is not fair that I should try them free.

I am, Sirs, yours truly,

April 29th, 1895.

KATIBUTION.

“PUBLIC AND PRIVATE VACCINATION.”

To the Editors of THE LANCET.

SIRS,—I can confirm the statement of “Public Vaccinator” that there is a vast amount of inefficient vaccination done by private practitioners. A few years ago I had a child of my own vaccinated in four places notwithstanding the protests of several female relatives, and have since then been supplied with numerous instances where vaccination has been done in two or three places only by practitioners of good reputation, while no instances were to be found of vaccination in four or five places by a private practitioner. This statement concerns a town not forty miles from London with a good sanitary record. For obvious reasons I do not wish to name it, but shall be pleased to give you the name privately if you wish. I enclose my card and beg to remain,

Yours faithfully,

April 26th, 1895.

PHYSICIAN.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester and Salford Sanitary Association.

THE annual meeting was held on April 24th, the chair being taken by the Lord Mayor. In moving the adoption of the report the Lord Mayor said that the association had done, and was doing, good work. The Bishop of Manchester, who seconded the resolution, said the question of sanitary improvement had become one of great urgency in consequence of the numerous changes which had taken place in the population during the last century. More and more the people were massing themselves in the great towns, and the degree to which this had occurred might be judged by the fact that Yorkshire and Lancashire with the counties north of them contained more people than the whole of England and Wales did at the beginning of the present century. Sanitary improvement was a national question, for if the people were dwarfed and stunted and the health deteriorated “they would be less able than heretofore to bear the burden of national labour and defence.” But they need not be dwarfed and stunted unless they neglected sanitary precautions. He enforced the duty of each one as being his brother’s keeper, and said that “if we refused to do our duty by our brother we should justly and most certainly suffer for it.” Sir Henry Roscoe, M.P., moved a resolution approving of the work of the association and of its deserving more adequate support. Dr. Simpson moved that a Smoke Abatement League be formed, and that the nucleus of the league consist of the organisations at present existing in Manchester, Rochdale, Middleton, Oldham, and Bolton, and that the committee of the Manchester and Salford Noxious Vapours

Abatement Association (a branch of the Sanitary Association) be requested to take immediate steps for the formation of a committee of management. This was seconded by Mr. Charles Roberts of London and carried unanimously.

Sanitation in Prehistoric Times.

A numerous attended conversazione was held at Owens College on the 23rd ult. in connexion with the sanitary conference to open the day following. During the evening Professor Boyd Dawkins gave an interesting and amusing address on the Indications of Sanitary Progress in Prehistoric Days. The very earliest man of the pliocene age was only distinguished from the wild animals about him by being clever enough to fashion implements and use fire, and it could not be said that he was sanitary or insanitary. His successor, palæolithic man, was the user of the polished stone axe, the introducer of the domestic animals, he had a fixed habitation, and he invariably chose dry areas for habitation. In the neolithic man we have the first evidences of his living in a community, but the refuse was left in his habitation and he was ignorant of water-supply. He always selected, however, those spots where there was natural drainage, and he was the first tiller of the ground. The most important developments of sanitary appliances are found at the close of the bronze and in the iron age. There was a most elaborate system of refuse heaps, particularly shown in certain camps that had been explored by General Pitt Rivers, and especially in one near Lewes. But there was no evidence of any artificial water-supply. “But neither in the neolithic, the bronze, nor the prehistoric iron age were there any interments allowed within the area of habitation.” In the bronze age evidence that cremation was the rule was to be found in the limestone ranges of Derbyshire and the chalk downs of Wiltshire.

Conference on Sanitary Progress and Reform.

This took place in the town hall by the kind permission of the Lord Mayor, and the first meeting was held at the close of the annual meeting of the Sanitary Association on Wednesday last. It was opened by the delivery of an inaugural address by Dr. Simpson, chairman of the association, in which he sketched the gradual improvement of the health of Manchester and the possibilities of still further progress. The subject of smoke abatement was next considered. Sir Henry Roscoe, who had taken the chair, said that while the smoke from manufacturing operations had been chiefly considered there was the larger question of that from household fires, which was a most difficult one. Mr. A. E. Fletcher, chief inspector of alkali works, gave an address on Air Pollution, in which he urged that the compulsory powers given under the Alkali Acts to inspectors in regard to vapours from chemical manufactories should be given in relation to coal smoke. He gave numerous instances to show that the emission of smoke from such chimneys was not necessary. In one case, where there were eleven boilers, there was only smoke for two and a half minutes in ten hours of continuous observation. Nor was the consumption of smoke effected at a loss. In one case the owner said he had effected a saving of 10 per cent., as cheaper coal could be used satisfactorily. The question of domestic smoke was far more difficult. We like open fire-places and the blaze of the smoky coal. In his own house he had a stove in the basement by means of which he introduced a stream of warmed air into the rooms, and was able in consequence almost to dispense with fires. Mr. Herbert Fletcher of Bolton presented the report of a Committee of the Noxious Vapours Abatement Association on the testing of smoke preventive appliances. It would have been issued earlier but for lack of funds, as the steam users in whose interests the work was undertaken had not given the support that was anticipated. The committee organised a series of observations of all the principal chimneys of two representative Lancashire towns—Bolton and Oldham—where great attention had been paid to the subject through public and private prosecutions, and where a greater variety of appliances were in use than in any other towns. The condition of 179 chimneys was noted once every minute. The whole-day observations had enabled the emission of smoke from two representative towns on a summer’s day to be expressed for the first time numerically, and had thus afforded a correct basis of comparison by which to estimate the relative importance of the various degrees of smoke abatement claimed by the appliances

¹ Dr. Simpson’s address is published in another part of our present issue.—ED. L.

¹ Second edition, vol. ii., p. 339.

or methods of firing. The general average of 179 chimneys was 102 minutes each in ten hours, varying from 423 in the worst to 4 in the best. The report, which is of an exhaustive character, has not yet been printed. The Chairman (Sir H. Roscoe) said it had now been proved that manufactories could be carried on without the emission of black smoke. "That was an important result to have arrived at." In the afternoon Mr. Herbert Phillips spoke as to the objects of the Smoke Abatement League, the formation of which was decided on at the previous meeting. It was expected that besides those already named other towns would join shortly. The work of the league was simple. It was shown that the nuisance was unnecessary and the law must be put into force. He believed that people only required to be convinced that the nuisance was preventable and that they would support those who took action. Mr. Cohen of the Yorkshire College spoke of the work done in Leeds and urged the appointment of Government instead of local smoke inspectors—men of scientific attainments who would not condemn unless they had adequate cause for doing so and who would give advice when required. Other gentlemen continued the discussion, and Mr. Horsfall said that in Ancoats the enforcement of the law was a farce. His own house was practically smokeless, and he used an old method for which there was no patent—the grate of the late Dr. Neil Arnott. Dr. G. H. Bailey of Owens College read a paper on the Air of Schools, in which he described the results of examinations of the air of certain elementary Board schools in Manchester and Salford, for which facilities had been given by the School Boards. They were made in summer and he hoped to repeat them in the winter. Even though the windows were kept open the whole of the school-time the air in the largest and best rooms had a very distinct odour, while in the class-rooms it was very oppressive, giving rise to headache where it had to be endured for half an hour together. In some of the schools matters were much worse; three were named where the excess of CO₂ was, as a rule, 12 to 15 in 10,000, and the odour, in the class-rooms especially, simply unbearable. It was clear that, even under favourable conditions, the fresh air supply was too limited. Mr. E. Hewitt read a careful paper on the Warming and Ventilation of Schools. Out of six in Manchester and Salford he only found one in which there was any adequate attempt at a scheme of ventilation. He advocated a mechanical as distinguished from the "natural" system. Mr. W. Spinks of the Yorkshire College followed with a paper on the Drainage and General Sanitary Arrangements of Schools which was of a very practical character. Dr. Emrys Jones gave an admirable paper on the Lighting of Schools, and on the evils produced by imperfect light—myopia, asthenopia, and spinal curvature. The best aspects for windows were east and west, and the light should come from the left of the pupil. Extra-good light should be provided for the girls' sewing classes, and a room lighted from a glass roof would be the best. He urged the use of the electric light in all schools. He said that not 5 per cent. of the schools in Manchester and Salford would stand a most moderate test of efficiency as regarded lighting. The Dean of Manchester, who is Chairman of the School Board, said he could not sufficiently express his thanks for Dr. Emrys Jones's paper, notwithstanding the severity of his lash, and would bear in mind what he had been told. On Thursday, the 25th ult., papers were read for Cardinal Vaughan and Lord Meath, both of whom were unavoidably absent. Lord Meath's paper was on Open Spaces for Recreation. In London there was an acre of open space for 768 inhabitants, but there was still a crying need for more breathing spaces. Though Manchester has done a good deal no one could pass through the streets of the city without seeing there was need for more being done if she were to have a low death-rate and a high average of physical health, strength, and happiness. He advocated large parks, but more especially small playgrounds divided into two portions—one for boys and the other for girls and small children. Cardinal Vaughan's paper dwelt on the need for winter recreation halls for the poorest localities capable of accommodating 500 or 1000 people, well heated and lighted, and where music and entertainments, with refreshments at cost price, should be provided on certain evenings in the week. In the discussion which followed the general opinion seemed to be that the cost of providing music &c. for places so small would be prohibitory. Mr. Charles Roberts gave an exceedingly interesting and comprehensive address on Recreation generally. It was illustrated with

diagrams showing how till about the age of ten boys and girls advanced in growth *pari passu*, and then that for two or three years the girls shot ahead, but after that were passed by the boys, who then kept the lead. In strength, however, the boys always stood first, and their recreations and games should be duly proportionate. He placed running at the head of out-door exercises, and spoke favourably of fencing, military exercises, boxing, wrestling, billiards, and dumb-bells for in-door recreations. He thought there was a danger lest the children should forget how to play, and mentioned games, such as rounders, which had become almost forgotten. In the afternoon of the 25th ult. a large audience, chiefly of ladies, met to discuss the subject of Women's Work in Sanitary Reform. The first paper was read for Mrs. Hardie, president of the committee of the Manchester Ladies' Health Society, in which the great advance in sanitary matters was acknowledged. "It was doubtful, however, when they contemplated the densely populated districts of Manchester and Salford and compared them with the condition of things when fish could be caught in the Irwell near the Cathedral, and when Greenhey and Kersal Moor were really rural spots, whether improved knowledge and laws had made up for what we had lost." She then gave details of the work the society had carried on, and appealed to the ladies of the district for personal help. Mrs. Charles Hughes addressed the conference on the teaching of home nursing, as distinguished from nursing as practised in hospitals and by the trained nurse. The great difficulty was the ignorance of the people, "who had no idea of the most ordinary cleanliness, and whose notions of comfort consisted of the very barest remove from poverty and destitution." Mrs. Clay said the ignorance of the people in sanitary matters was simply appalling. She moved, and it was seconded and resolved, "That the necessity of cottage bath-houses fitted with warm baths in the densely populated parts of Manchester having been forced upon the attention of the Ladies' Health Society, this conference is of opinion that the corporation would confer a great benefit upon the people by providing such bath-houses"; and a deputation was appointed to wait upon the Baths Committee of the corporation, with a view to obtain the carrying out of the resolution. The proceedings of Friday consisted chiefly of an address from Sir B. W. Richardson on Sanitation: a Review of the Past, and an Ideal for the Future. Dr. Simpson presided. The address was too important to allow of any attempt to sketch even its outlines, but no doubt it will before long be published in an accessible form. Dr. A. W. Ward, Principal of Owens College, proposed a vote of thanks to Sir B. W. Richardson for his able and impressive address. He said they desired to thank him, not only for the admirable address he had delivered, but for the life's work which that address embodied. It was seconded by Mr. T. C. Abbott, a member of the corporation, who drew attention to the fact that Manchester might be credited with having been the birthplace of one of the founders of modern sanitary science, the late Sir E. Chadwick. The resolution was carried by acclamation. In a brief reply Sir B. W. Richardson pointed out that nothing he had advanced as to the ideal future was so remarkable as many things which had occurred in the past hundred years. With the customary votes of thanks the conference concluded.

May 1st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Muirhead Trust.

THOSE trusting University reformers who believed that the operation of the Universities Act would rapidly be followed by the application of numerous colleges to the various Universities have recently had a series of disappointing experiences. The agreement between University College, Dundee, and the University of St. Andrews has been pronounced illegal by the House of Lords. Queen Margaret College, which at one time appeared to be on the eve of affiliation with the University of Glasgow, suddenly changed its policy, gave up all independent existence, and allowed itself to be absorbed by the University; and now negotiations between the same University and the proposed Muirhead College have come to a deadlock. It may be remembered that the late Dr. Muirhead of Cambuslang left a sum of money, amounting to £30,000 or thereabout, in the hands of trustees for the

purpose of founding an institution for the education of women in medicine and in the physical and biological sciences. In a codicil it was suggested that this "Muirhead" College should be built near to the Victoria Infirmary. As Queen Margaret College was already in existence for the purposes proposed in Dr. Muirhead's will, the trustees approached the University Court with a view to devise, if possible, some joint scheme by which opposition between the University and the Muirhead College should be avoided. After several conferences the trustees offered certain proposals in which they suggested that the first two years of medical education should be provided by the University at Queen Margaret College, whilst the remaining three years should be undertaken by the Muirhead College, to be erected in the vicinity of the Victoria Infirmary, where the necessary clinical instruction could be obtained. This scheme would prevent the institution of two colleges competing with one another in a comparatively limited field, and would secure to women students—free from the intrusion of the opposite sex—the necessary lectures and laboratory instruction in the immediate neighbourhood of a well-equipped hospital. The University Court, however, acting on the report of a committee concerned in the negotiations, has rejected the proposals of the Muirhead trustees and has refused to put forward any counter-propositions. Whatever view may be taken of the refusal of the court to submit a scheme of its own, it can scarcely be questioned that there are valid reasons for its action in rejecting the proposals of the trustees. Apart from the difficulty incident to a system of dual control, and of making in practice a cleavage between the first two and the last three years of the medical curriculum, the proposal made by the trustees involves the renunciation on the part of the University of its right and duty to give to certain of its students instruction during the last three years of the medical curriculum, and to this the University could not be expected to assent. On the other hand, the responsibility for the non-success of the negotiations must not be placed entirely on the shoulders of the Muirhead trustees. They, of course, are bound by the terms of the will, and these seem to compel them to establish an independent institution in the neighbourhood of the Victoria Infirmary, so that the basis for their action is limited. There are also other clauses which may possibly cause difficulty in any scheme for coördinate work between the College and any other institution. Thus Dr. Muirhead does not wish any clergyman to have anything to do with the management of the College, on the ground that "creeds are the firmest fetters to intellectual progress," and medical men, we understand, are also forbidden, for a reason equally complimentary and suggestive. In any case it is a matter for regret that influences which might in combination have placed Glasgow in an altogether exceptional position as a centre for the University training of women students in science and medicine are likely to drift into mutually disadvantageous opposition.

Glasgow University.

Dr. Thos. Barr and Dr. Walker Downie, the recently appointed Lecturers on Diseases of the Ear and Throat respectively, were on April 26th introduced to their classes by Professor Gairdner, the Dean of the Medical Faculty. Each lecturer delivered an introductory address. In consequence of indisposition Professor Simpson has been granted a prolonged leave of absence, and the duties of the chair of Forensic Medicine are being discharged by Dr. T. K. Dalziel, who is assisted by Dr. Gavin McCallum. Dr. A. Maitland Ramsay has been appointed by the University Court to lecture on Diseases of the Eye to the students at Queen Margaret College.

The John Reid Prize.

The trustees of this prize have awarded the sum of £10 to Dr. Alex. Maclellan, Glasgow Western Infirmary, in recognition of the merits of his thesis on "Some New Methods for the Purification of Artificial Salicylic Acid."

Glasgow District Lunacy Board.

The position of consulting physician to the new asylum at Gartloch has been accepted by Dr. Alex. Robertson, and that of superintendent by Dr. L. R. Oswald. The latter has for several years been senior assistant to Dr. Yellowlees at the Royal Asylum, Gartnavel.

Small-pox in Glasgow.

Small-pox has been a recognised quantity in Glasgow since

the beginning of the year, but has been kept within limited bounds by the energy of the sanitary authorities. Recently, however, the number of cases has shown a disagreeable tendency to increase, and there are now sixty-three cases in the hospital. Most of these come from the western district, and in one street is a tenement, usually occupied by thirteen families, now completely deserted, the inhabitants having been removed either to the hospital or to the reception house.

Police Appointments.

Dr. Jno. A. Boyd has been elected a casualty surgeon to the Glasgow western district. The salary is £50 per annum. The Health Committee of the Police Commission has recommended that the salary of Dr. A. K. Chalmers, the junior medical officer of health, be increased from £400 to £500 per annum.

April 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Queen's College, Belfast: the New Laboratories.

THE erection of a large new block of buildings to be devoted to physiology and pathology is just being commenced at Queen's College, Belfast. An excellent site has been selected for it adjoining the existing medical buildings and the lately erected chemical laboratories, with both of which it will ultimately communicate. The ground floor will be devoted to physiology, which will have a large practical class-room, lecture theatre, physiological chemistry room, and professor's private work-room &c., all supplied with fittings and apparatus of the most approved type. The first floor will be given up to pathology, which will be provided with practical class-room, lecture theatre, private laboratory, general work and research room, culture room, &c. The building is to be heated with hot water. It is being built by the Board of Works, according to plans prepared by Mr. Robert Cockrane, F.S.A., in which the ideas of Dr. W. H. Thompson and Dr. J. Lorrain Smith, who are respectively at the head of the departments of physiology and pathology in Belfast, have largely been embodied. The new buildings will undoubtedly prove a most valuable acquisition to the medical school and the entire college. It is expected that they will be ready for occupation next year.

The Belfast Hospital for Sick Children.

The out-patient work having increased very much of late, the staff have recommended the board of management to appoint two additional members—an assistant physician and an assistant surgeon.

Oil-lamp Accidents in Belfast.

Accidents of this nature have become very frequent in Belfast of late. On Monday, April 29th, one of the ambulance waggons brought to hospital a woman who just before midnight was in the act of extinguishing a paraffin oil-lamp when it exploded, the result being that her clothes became ignited, and in a few minutes she was enveloped in flames. Two policemen after a time succeeded in putting out the flames, but not before the poor woman had been very badly burned. On the same evening an inquest was held in the Belfast Royal Hospital in reference to the death of a woman from the effects of burns received at her residence on the previous Wednesday by the explosion of an oil-lamp. Her son had also died from the same cause. The jury in their finding added a rider requesting the coroner to communicate with the Members of Parliament for Belfast and the counties of Down and Antrim with the object of calling the attention of the Government to the many cases of accidents which occurred in the city of Belfast and elsewhere from oil-lamp explosions, and requesting the Government to carry out the recommendations of the Select Committee upon Petroleum which reported last session.

Epileptics in the Belfast Workhouse.

This vexed question has cropped up again. It seems that a man aged forty-four was admitted to the workhouse on April 22nd and died there on the 25th. There is no reception-room for patients at the workhouse, but they are examined in a hall which is a public place, and when examined they are classified and sent to various departments of the house. This man was seen by two of the resident staff in consultation and they came to the conclusion that he was

an epileptic (from the history given them by his wife and from their personal observation), and that he was insane or of weak mind. Accordingly they sent him (as they stated, they had no other option) to the epileptic ward, where he died. An outside dispensary officer said he treated him before admission for epilepsy. He had never seen him in a fit, but his wife told him he had them. When he saw the man he was suffering from congestion of the brain. He did not observe any signs of insanity about him, but thought the best place he could be sent to was the workhouse. At the conclusion of the evidence the coroner dwelt very fully on the various aspects of the case; the jury found that the man came to his death from congestion of the lungs in the lunatic department of the Belfast workhouse. They requested the coroner to forward copies of the evidence to the Local Government Board and Belfast board of guardians, and to request them to hold an inquiry into the whole circumstances of the case. They further said that, in their opinion, such an inquiry is necessary. "They also strongly recommend that a proper room be provided for the reception of patients while being examined, as it is cruel to do so in the public part of the infirmary."

Typhus Fever in Belfast.

The outbreak of typhus fever has not yet been stamped out. Within the last fortnight about six cases have been reported to the medical superintendent officer of health, most of them coming still from the Falls district, where the disease was first noticed. A case admitted from another part of the city to the Fever Hospital has been traced to infection from the original *locule* of the outbreak in the Falls part of the city.

The Battle of the Clubs at Cork.

All sorts of subterfuges are had recourse to for the purpose of getting the ordinary practitioners into consultation with the new club officers, but so far without result. Last week a medical gentleman was requested to see a patient, but on questioning the messenger he ascertained that no less than three of the newcomers were actually in attendance, and he promptly declined to see the patient unless the services of the three were dispensed with. It may be well to explain that with a view of saving the poorer club patients from their own folly it has been arranged that when an ordinary practitioner is in attendance he is to be at liberty to call in the assistance of a consultant gratuitously if the patient should be unable to pay for a second opinion. This sounds very like returning good for evil. A club patient in receipt of about £500 a year died recently. His poorly-paid club officer had visited him for a considerable time, and as his condition became serious the club officer withdrew and two other medical men took charge of the case. I cannot help thinking that had I been in his place I should have preferred the services of a practitioner who could have continued in attendance and who would be in a position to give the consultant a full history of the progress of the disease. Another apple of discord is about to be thrown amongst us. The Victoria Friendly Legal Association, hailing from one of the large English centres, has announced its intention of endeavouring to form a provident dispensary in Cork. The proposal of the association is simplicity itself. Anyone, no matter what his income may be, is to be at liberty to become a member of the dispensary, and on paying one penny per week is to be entitled to the services of the medical officers of the dispensary. Even that small remuneration is not to be given to the medical men, but is to be distributed between them and the association. Should the general profession in Cork decline to avail themselves of this beneficent commercial project the imported medical men are to be requested to affiliate themselves with the association, and should they refuse the terms other medical men are to be introduced into the city. I have no doubt the reply of the general profession in Cork will be given in no uncertain tones. Can there be any stronger argument in favour of the combination existing in Cork? In all humility I suggest that the Cork men have given a lead which, in the interests of humanity, ought to be followed by other large cities, for it is clear to me that if the remuneration of the profession should continue to diminish to a vanishing point young men of talent and industry will not enter the profession, and the great bulk of those already in it will have neither the time nor the energy to advance medical science. So the "penny wise and pound foolish" policy must necessarily recoil on its authors—the general public. Surely the General Medical Council is not a wholly impotent body. Can it do

nothing to maintain the dignity of the medical profession and to safeguard the highest interests of the State?

Cork Societies' Medical Officers' Indemnity Fund.

The following additional subscriptions have been received by the treasurer, Mr. D. D. Donovan:—Surgeon-Major Thornhill, Indian Medical Service, £1 1s.; "Nec Opprimere nec Opprimi," £1 1s.; Dr. Dundas Grant, London, £2 2s.; Dr. Justin F. Donovan, Spanish Town, Jamaica, £1 1s.

(FROM OUR OWN CORRESPONDENT.)

Abdominal Hysterectomy—a New Method.

M. RICHELOT¹ has devised an original and improved method of performing this operation. He claims for his procedure great advantages over the current methods, which are long and laborious, and the quicker methods sometimes employed, which are frequently attended with danger. The principal advantage of M. Richelot's manner of operating lies in the complete absence of ligatures and sutures, forcipressure only being used. A scalpel, a dissecting forceps, a long and a short hæmæstatic forceps, and finally two long Richelot's forceps provided with a long "bite"—this is the only armamentarium necessary. The patient is placed on her back and the operator takes his station between the separated limbs. The vagina is first thoroughly disinfected, for in the course of the operation the surgeon's hand passes alternately into that canal and the abdomen. The usual abdominal incision being made, the uterus is enucleated and laid on the abdomen, covering the lower angle of the operation wound. [When fibromata occupy the lower segment of the organ the usual fragmentation is at once practised; when, however, they are interstitial they are left untouched, and the operation is proceeded with as follows.] An anterior peritoneal flap is fashioned by means of an incision across the anterior surface of the uterus, extending from one broad ligament to the other. The broad ligaments are thus liberated and thrown downwards over the bladder. The left index finger is introduced into the vagina, and the anterior cul-de-sac is incised with a large pair of scissors, the dissection of the vagina being pushed nearly as far as the sides of the os. Then, leaving the uterus *in situ*, the broad ligament on one side is seized by the hand quite close to the uterus, an opening in the posterior cul-de-sac is made with the point of the scissors, and through this orifice is passed, *per vaginam*, the posterior limb of Richelot's forceps, the anterior limb being thrust through the corresponding hole in the anterior cul-de-sac. The forceps is then thrust from the vagina from below upwards and, guided by the hand holding the broad ligament, is placed on that ligament. The same manœuvre is practised the other side by means of the second pair of Richelot's forceps. Both ligaments being seized by the forceps, they are liberated from their extreme attachments. The uterus now hangs only to the posterior cul-de-sac, which is in its turn divided with a few snips of the scissors. But as this section gives rise to hæmorrhage three hæmæstatic forceps are here placed. A plug of iodoform gauze is inserted into the upper part of the vagina, none being placed in the abdomen. The abdominal incision is sutured and the operation is over. Of five hysterectomies thus practised by M. Richelot, four being for fibromata and one for cancer, the four first mentioned were successful. The duration of the operation varies from thirty to thirty-five minutes, and no complications need be feared during the healing process. M. Richelot gives to his method of operating the somewhat cumbersome name, "hysterectomie par pinces vaginales d'emblée sans ligature ni suture."

A New Process of Water Purification.

I have from time to time communicated to your readers methods stated to be efficacious for rendering safe the drinking of spring water. If we may believe M.M. Girard and Bordas the most efficient sterilising process has been discovered by them. The water is first treated with permanganate of calcium, and then filtered through peroxide of manganese. It appears that the calcium permanganate—a salt easily manufactured—is, in the presence of organic matter and micro-organisms, decomposed into oxygen,

¹ Société de Chirurgie, April 24th.

manganese oxide and lime, and the organic matter and the bacteria are thus destroyed. But in order to further increase this oxidising power, and at the same time destroy the excess of calcium permanganate added to the water, this latter is filtered through a layer of manganese peroxide. The filtered water is perfectly limpid and is entirely free from pathogenic and other micro-organisms and from organic matter. The simplicity of the process tells greatly in its favour.

"Anglisch Pharmacy as She is Exercised."

I had recently occasion to prescribe for a leading member of the English colony a purgative dose thus formulated (*Pharmacopœia Britannica*): Pil. hydrarg., 2gr.; ext. coloc. co., 6gr.; euonymin, 1gr.; ext. hyoscyami, 1gr.; divide in pil. 3 (silvered). The three pills to be taken to-night at bedtime. Three hours after the pills had been taken violent griping and purgation set in, the colic continuing at intervals for several hours. I learned that the druggist who had prepared the pills was one of those enterprising French tradesmen who, on the strength of possessing a copy of "Squire's Companion," and of retaining the occasional services of an English assistant, dub themselves "English chemist." On asking to be shown the compound extract of colocynth employed I was handed a pot of powder labelled "Pulv. pro. pil. col. co.," and hailing from a French wholesale establishment. I had the same prescription made up at a respectable English druggist's, and swallowed the pills myself last night without any suspicion of griping during the night. The frequent occurrence of such grave mistakes induces me to repeat the warning I have so often given to my compatriots not to have English prescriptions prepared at an establishment where the principal is a foreigner. In the shop above mentioned there was no English assistant, nor could anyone in the establishment speak a word of our language. When the Englishman comes abroad let him forget for the nonce the stores tariff and avoid risking his life by having prescriptions prepared at an establishment where the principal and his assistant are of the same nationality as himself.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The late Professor Ludwig.

PROFESSOR KARL LUDWIG, one of the greatest physiologists of Germany, died in Leipzig on April 25th. He was born in 1816 at Wittenhausen, and took the degree of Doctor in 1839, afterwards becoming *privat-docent* in 1842 at the University of Marburg. To his town he left in 1849 for Zürich, where he stayed for six years as Extraordinary Professor. In 1856 he was appointed Ordinary Professor at the abolished Academy for Army Surgeons in Vienna. For the last thirty years he was Professor of Physiology in the University of Leipzig, which owes to him no small part of its renown. At a very early period of his academical career he opposed all the transcendental theories in physiology which were then in vogue, and his first published work entitled "The Mechanism of the Secretion of Urine," explained the formation of urine in the kidney on merely mechanical principles. He improved physiological methods by the introduction of apparatus for the graphic recording of results, the most notable being probably the kymograph. He was the author of important researches on the circulation of the blood, on the influence of respiration on the circulation, and on the action of the medulla oblongata on the circulation. He also made very valuable researches on the part played by the nervous system in glandular secretion. Not only physiology but also pathology and clinical medicine are greatly indebted to him. Among his pupils need only be mentioned the late Professor Cohnheim, formerly one of the leading pathologists of Germany. The Physiological Institute of Leipzig, of which Professor Ludwig was the director, was a centre of attraction not only for students but also for graduates, who came there from all parts of the world to study under his direction. Professor Ludwig's name will ever hold an honoured place in the history of medicine.

The Appointment of Privat-docents.

Publicity has been given to a rumour that the Government intends to change the regulations affecting the appointment

of *privat-docents*. Hitherto a scientific man who desired to hold this position had to apply to the board of his faculty, giving an account of his past studies and presenting a new work for the approval of the board. If the faculty thought him competent to be a university teacher he was admitted, and the so-called "habilitation" was conferred on him at a formal sitting, with the Dean in the chair and all his friends present. The Government took no part in the matter, but was informed afterwards by the Dean that Dr. X— had been "habilitated" as *privat-docent*. It is now reported that the Government desires to have a voice in the admission of *privat-docents*, and wishes the faculties to obtain its permission before the "habilitation." Political reasons have induced the Government to take this step. Many *privat-docents* belong to the Social-democratic party, and the Government considers this to be dangerous for the progress of science and the tranquillity of academic life. One of the *privat-docents* at the philosophical faculty of the University of Berlin is a well-known leader of the above-named party, and the Government has already once expressed its disapproval, but the faculty declined to take any measures for removing the lecturer from his appointment. It is incomprehensible that a Socialist should not be an accomplished teacher of physics, of Greek, or of surgery, but the Government seems to hold other views on this question. The rumour is contradicted by the official newspapers, but many persons believe it nevertheless.

An Antitoxin for Carcinoma.

In the last number of the *Deutsche Medicinische Wochenschrift* Professor Emmerich and Dr. Scholl of Munich publish the results of experiments on the treatment of carcinoma by a new antitoxin. Through the researches of Neisser, Fehleisen, and others it has become known that carcinoma is influenced for the better by erysipelas. Professor Emmerich now states that this influence depends on changes in the blood produced by the cocci of erysipelas, and he accordingly makes use of the blood serum of animals who have been previously affected with that disease. His mode of proceeding is to inoculate sheep with cultures of the cocci of erysipelas, and to abstract blood when they are in the stage of convalescence. The blood is then passed through Chamberland filters in order to remove the cocci, and finally put up in little tubes of ten cubic centimetres each. With this blood daily injections are to be made into the tumours—from 1 to 4 c.c. for small growths, and from 10 to 25 c.c. for larger ones. The patients treated in this way did not complain of any pain, the temperature did not rise above 38.5° C., and no other complications were observed. In nearly all the cases the general state of the patients became better and the tumours diminished. Professor Emmerich and Dr. Scholl say that they do not yet claim that their method is to take the place of operative procedures, but as very often an operator leaves small pieces of the tumour the injections would in those cases be capable of dispersing those pieces. They also say that they do not yet know whether their antitoxin is a general specific or whether it acts only against certain forms of cancer. Tubes with antitoxin can be procured from their laboratory, so that other medical men may try their method. As up to the present all specific cures for carcinoma have failed, the profession should be very guarded in forming an opinion as to the new remedy.

"Scholastic Reform in Germany."

The annotation under the above heading in the last issue of THE LANCET is, I am truly sorry to say, founded on a real French *canard*. It is a pity that no "differentiation between the youthful Teutons" is to be made either by their teachers or by the medical profession. As there are about 100 000 school children in Berlin, nearly a hundred physicians would have been occupied all the year round in conducting the mental examination. The emoluments of the medical profession being only moderate, no doubt the school managers would have found practitioners enough to undertake this rather tiresome work. In this way an improvement in the circumstances of many of our professional brethren would have resulted from the alleged reform described by the French authority.

April 30th.

PRINCESS MARY ADELAIDE has consented to open the new Paddington-green Children's Hospital on Monday, July 1st, at 4 P.M.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Italian Medicine at Montevideo.

ITALY is largely represented in South America, and in no direction more successfully than in medical science. Thanks to her influence, material and moral, Uruguay takes rank among the most civilised and prosperous of the republics and Montevideo among the most enlightened of cities on that continent. In Montevideo, by a law recently carried through Parliament, an institute modelled on that of Pasteur in Paris has been erected for the treatment not only of rabies and anthrax, but of diphtheria and tetanus by *sero-therapeutics*. Besides these special objects, the institute offers to the student of medicine the amplest means for scientific and clinical research in every branch of the healing art, and is already being resorted to by undergraduates and post-graduates from neighbouring republics for the facilities it presents for the higher professional qualifications. As director of the institute, on the unanimous recommendations of the local faculty of medicine, Parliament has invoked the services of Dr. Giuseppe Sanarelli of Siena, in which seat of learning he has held with much acceptance the chair of Hygiene. After a thorough training in the Parisian institute, in which he greatly distinguished himself, Professor Sanarelli worked hard at the etiology and course of infective diseases, turning his attention more particularly to prophylaxis and precautionary legislation. In recognition of his services in this field the Montevidean Government has given him, besides the direction of the local Pasteur Institute, the honourable post of Professor of Hygiene in the University, and, to compass this appointment, has even strained the consuetudinary law which discountenances the election of foreigners to such chairs. The salary in connexion with it is 20,000 francs, considerably in excess of the standard of remuneration customary in Italian seats of learning.

The Health of Florence.

An official return just to hand gives opportune evidence of the satisfactory hygienic conditions of Florence. The "Bollettino Sanitario del Comune" states that in the first *trimestre* of 1894 the deaths were 1535, and in the corresponding period of 1895 they were 1451, making a diminution of 84. In this period in 1894 there died from measles 12, from typhoid fever 9, from diphtheria 26, and from pulmonary tuberculosis 158, making a total of 205 deaths. In 1895, on the other hand, there died from scarlet fever 5, from typhoid fever 7, from diphtheria 14, and from pulmonary tuberculosis 144, the total mortality amounting to 170. It will be seen in the diminution of the mortality in general over that period from the first *trimestre* of the preceding year that the infective maladies have shown a reduction of 35.

The "Cosmic Microbe."

The series of lectures in progress at the "Circolo dei Naturalisti" (Naturalists' Club) was continued on the 25th ult. by Professor Sanarelli. His theme was "Il Lavoro Utile dei Microbi nella Società" ("the Useful Work of Microbes in the Social Economy," or, to put it shortly, the "Cosmic Microbe"), and he dwelt, in a thoroughly Darwinian spirit, on the benificent activity of microbes in the soil, the air, the water, in human alimentation, in human habits, in the propagation and evolution of the human species, and even in infective maladies themselves, in all which spheres they exercise a function which, as being natural, is at once benificent and indispensable, the arrest of which would imply the rapid disappearance of animated creation from the terraqueous globe. Professor Sanarelli, from the researches begun at the Pasteur Institute, followed up at Siena, and soon to see the light in Montevideo, drew many striking illustrations of the part played by microbic life in biology and claimed, as one of the future achievements of science, the organisation and control of the inexhaustible, hitherto unutilised microbic forces, and the turning of these to practical account for the evolution of humanity in all its interests, individual and social. We are, according to Professor Sanarelli, on the threshold of discoveries which will revolutionise our dealings with the human organism in health and disease, widen our social horizon, and elevate and refine our common civilisation. The lecture, an attractive specimen of biological culture and speculation, was listened to with

rapt attention by a numerous and distinguished audience, in which the Roman school, its teaching staff, and its practitioners, consultant and general, was largely represented.

The Cavaliere Rosati.

A great loss has befallen Italian surgery in the death of the Cavaliere Tebaldo Rosati, for many years a clinician and consultant of the highest authority in the Tuscan school. In Florence, at 10 o'clock this morning, he succumbed to what in Italian classification is given as "paralisi cardiaca" (paralysis of the heart) just a few minutes before his colleagues, Drs. Marcacci and Paoli, hastily summoned, arrived at his bedside. The Cavaliere Rosati was in his sixty-fourth year, and was "Chirurgo Primario" (Senior surgeon) of the two Florentine hospitals, the Santa Maria Nuova and the San Giovanni di Dio. He was a brilliant operator and sound teacher, and his presence at the various medico-chirurgical congresses, provincial, national, and international, was often made memorable by original communications of his own and by able and suggestive criticisms of those of others. Courteous, scholarly, and refined, very popular with his students, and always pleasant to meet in consultation, his departure is deeply regretted by the many who knew him as a professional brother or adviser as a citizen, or as a friend.

April 29th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Sweating System.

A LEGISLATIVE investigation into the effects of what is known as the "sweating system" is in progress. By the "sweating system" is understood the custom of occupying living-rooms in tenement houses for the manufacture of clothing, cigars, &c. Large numbers of operatives are crowded into living-rooms where they make clothing for the wholesale houses. The effects of this crowding upon the health of the persons employed have proved most disastrous; when cigars and cigarettes are manufactured the air of the whole house becomes very impure. The manufacture of clothing in these crowded living-apartments has resulted in the spreading of contagious diseases. Many instances have been narrated of the spread of scarlet fever, diphtheria, measles, and small-pox by means of the clothing made in rooms where children were suffering from these diseases. Inspectors have found the manufactured clothing used as the bed-covering of children suffering from contagious diseases. Outbreaks of small-pox and scarlet fever traceable to the clothing made in tenement houses are not infrequent. In some instances these occurrences are reported in other and remote States. The result of these investigations will no doubt be the enactment of stringent laws against the practice of opening workshops in tenement houses.

Permanent Establishment for the Cure and Prevention of Hydrophobia.

The Legislature of the State of New York has before it a Bill to make permanent provision for the treatment of poor persons duly certified by regular physicians to have been bitten by rabid animals or otherwise put in danger of infection with rabies. The measure provides for the transportation at the public expense of such persons with necessary attendants to the Pasteur Institute in the city of New York to enable it to provide for these patients during the time of their treatment.

Emigrant Inspection on the Russo-German Frontier.

The establishment of control stations for emigrant inspection on the frontier between Germany and Russia is to be participated in by the American line of both the New York—Southampton and Philadelphia—Liverpool services. These lines have now made arrangements to have all their passengers coming from Russia admitted to the stations at Ilowo, Ottlotschin, Prostken, Eydtkuhnen, and Bajohnen in order that they may pass the same rigorous examination and at the same time have their baggage properly disinfected. The American line has agreed to participate in the maintenance of the establishments at a considerable annual expense, with a view of fully insuring itself against the importation of any infectious disease, inasmuch as only those passengers from

Russia will be allowed to pass through Germany to Southampton and Liverpool, on their way to the United States, who are provided with a passport entitling them to proceed on their journey through Germany, issued to them only after having gone through the requisite quarantine at those stations.

Discussion on Antitoxin.

At a recent meeting of the New York Academy of Medicine antitoxin was the subject of discussion. The bacteriologist of the Board of Health read a paper commending the use of antitoxin, and reporting favourably on the results obtained in the Contagious Disease Hospital of the Board. The physician of the hospital reported at length on the use of the remedy, and gave a summary of the recoveries from its use. A third paper was devoted to the methods of cultivating the antitoxin, and interesting instructions were given as to the selection of the horses best adapted to give an active and reliable agent. This paper was the more important as the Board is now authorised to place the remedy on the market. The last paper was read by the resident physician of the Infant Asylum, who gave an interesting account of the arrest of an epidemic of diphtheria in that institution by the general treatment of the patients with antitoxin. In the discussion which followed one of the visiting physicians of the Contagious Disease Hospital of the Board of Health stated that he had witnessed the use of antitoxin and carefully observed its effects. He asserted very positively that its value was greatly overrated. In the severe cases he saw no improvements that could not be properly and justly attributable to the other remedies employed, and the milder cases recovered in the usual manner. This declaration created a marked sensation in the large medical audience, and it was apparent that the question of the actual value of antitoxin was again relegated to the domain of uncertainty.

To Prevent Blindness.

Laws to prevent ophthalmia neonatorum are being adopted in many of the United States. The first impulse in that direction was given by Switzerland as early as 1865. It was enforced by Professor Horner, and as a result no child has entered the large blind asylum of Zürich who had become blind since 1865 from this cause. The necessity of such laws in this country is apparent when I state that it is estimated that there are upwards of 10,000 persons blind from the infection of the eyes at birth. At the Sloane Maternity in New York, where asepsis is rigidly enforced, no case of disease of the eyes of the new-born of any severity has occurred in 4000 births in the last six years. But outside of well-managed maternities the cases of ophthalmia neonatorum continue to occur with far too great frequency in spite of the laws made to prevent the disease. New York has had a law on this subject in force since 1890, but owing to the difficulty of enforcing it ophthalmic surgeons report that there is little diminution of the disease. The only hope of securing better results must be found in the rigid enforcement of laws regulating the practice of midwifery. This was done in Switzerland with the results above given.

Obituary.

SIDNEY ROBERTS WEBB, M.D. EDIN.,
OF THE CONGO BAPTIST MISSION.

WE regret to learn of the death, on his voyage home, of Dr. Sidney Roberts Webb, of the Baptist Congo Mission. A young medical man of great promise and geniality, who had profited by the advantages of a public school education and the subsequent medical course at Edinburgh University, his prospects at home were of the highest. But he was moved by the noble compassion which seeks to carry the best gifts of religion and of science to those who need them most, and accordingly took an appointment under the Baptist Mission, but without salary. He had just completed two years of successful work (in one day he saw 120 patients) and was returning for his first furlough, which by the rules of the society is taken at this early period to prevent the breakdown which is so apt to follow the first exhausting influence of the climate. So far as is known, he and his equally brave young wife left in excellent health, the brief telegram only announcing the fact

of his death on the 12th ult. while on his way home. He had endeared himself to his colleagues and his patients on the field, who, with all who knew him, have the comfort of knowing that his sacrifices were attended with delight to his own heart, and of believing that goodness and power like his will find alike reward and scope in some other sphere.

CARL T. THIERSCH,

PROFESSOR OF SURGERY AT THE UNIVERSITY OF LEIPZIG.

IN the death of Professor Thiersch another of the prominent leaders of German surgery, whose reputations were won in the campaigns of thirty and forty years ago, has passed away. Professor Thiersch was born at Munich in 1822 and had just completed his seventy-fourth year when he died on the 28th ult. After studying at Berlin, Vienna, and Paris he obtained his doctorate at Munich, his graduation thesis being on the Action of Drugs. He engaged as surgeon in 1850 in the 2nd Schleswig-Holstein campaign, when he served under Stromeyer, whose teaching and example had much influence on him. From 1848 to 1854 he was prosecutor in the Munich Pathological Institute; in 1854 he was appointed Professor of Surgery at the University of Erlangen, and was transferred thence to Leipzig in 1867, where he occupied the chair of Surgery for twenty-eight years. In the war of 1870 he was consulting surgeon-general to the 12th Army Corps (Saxon). His writings have not been numerous. Perhaps the most important was the monograph on Epithelial Cancer published in 1865, which was marked by great originality and advanced considerably the histology of epithelioma. His work upon Skin Grafting is also well known. He contributed an article to the first volume of the Pitha-Billroth Handbook of Surgery upon the "Minute Anatomical Changes following Wounds of Soft Parts," another histological study which opened up new conceptions of the healing of wounds. He was an earnest follower of the Listerian methods and will be remembered as a sound surgeon and one who was as scientific as he was practical.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Karl Ludwig, the well known Leipzig Professor of Physiology.—Dr. Fano, formerly Professor *agrégé* in the Paris Medical School.—Dr. T. Druhen, Honorary Professor in the Besançon Medical School.—Dr. Adolf Weil, Teacher of Odontology in the University of Munich.—Dr. J. R. Taylor, formerly Lecturer in Surgery in the Bellevue Hospital Medical College, New York.—Dr. Rydel, Professor of Ophthalmology in the University of Cracow.

Medical News.

CAMBRIDGE UNIVERSITY.—The following is the amended notice of the plan for the examinations for medical and surgical degrees, Easter term, 1895:—

FIRST EXAMINATION.

Part I. (Chemistry and Physics).—Friday, June 7th, 9 A.M. to 12 M.: Heat, Electricity and Optics; 2 to 5 P.M.: Mechanics and Hydrostatics. Saturday, June 8th, 9 A.M.: Practical Chemistry, and Oral Examination in Chemistry and Physics (in the University Laboratory). Monday, June 10th, 9 A.M. to 12 M.: Chemistry; 2 to 5 P.M.: Oral Examination in Physics (for those who do not take Biology). Tuesday, June 11th, 9 A.M.: Oral Examination in Chemistry and Physics continued. Wednesday, June 12th, 9 A.M.: Oral Examination in Chemistry and Physics continued.

Part II. (Elementary Biology).—Monday, June 10th, 2 to 5 P.M.: Elementary Biology. Friday, June 14th, 9 A.M.: Oral and Practical Examination in Elementary Biology (in the Biological Laboratory).

SECOND EXAMINATION.

Part I. (Pharmaceutical Chemistry).—Thursday, June 13th, 1.30 to 5.30 P.M.: Practical Examination in Pharmaceutical Chemistry (in the Chemical Laboratory). Friday, June 14th, 1.30 P.M.: Oral Examination in Pharmaceutical Chemistry (in the Chemical Laboratory). Saturday, June 15th, 9 A.M.: Oral Examination in Pharmaceutical Chemistry, continued.

Part II. (Human Anatomy and Physiology).—Thursday, June 6th, 9 A.M. to 12 M.: Human Anatomy, 2 to 5 P.M.: Physiology. Saturday, June 8th, 9 A.M.: Practical and Oral Examination in Anatomy (in the Anatomical School). Monday, June 10th, 9 A.M.: Practical and Oral Examination in Physiology (in the Physiological Laboratory). Tuesday, June 11th, 9 A.M.: Practical and Oral Examination in Physiology (in the Physiological Laboratory). Friday, June 14th, 9 A.M.: Oral Examination in Anatomy (in the Anatomical School).

The names of candidates for these examinations must be sent to the registry (through the prælectors of their respective

colleges) on or before Monday, May 27th. Forms on which it is requested that the names may be written will be sent to the prolectors. The certificates of candidates, accompanied by their postal addresses, must be sent to the registry on or before Saturday, June 1st. The fees for each examination must be paid to the registry when the certificates are sent in. The fee is £2 2s. for each part of the first and second examinations. Any candidate whose name and certificates have not been sent in and fee paid at the proper time is liable to pay an additional fee of £1 if he be nevertheless admitted to the examination.

The following gentlemen have passed the Third Examination for Medical and Surgical Degrees, Easter term.

Part I.—N. G. Bennett, B.A., John's; Biss, B.A., King's; Evans, B.A., Trinity; G. H. Field, B.A., Clare; Fletcher, B.A., Gonville and Caius; Hadow, M.A., Gonville and Caius; R. J. E. Hanson, Trinity; Hobday, B.A., Christ's; L. T. R. Hutchinson, B.A., Trinity; Key, B.A., Emmanuel; Lance, B.A., King's; Lawrence, B.A., King's; McCarthy, B.A., Gonville and Caius; H. J. May, B.A., Gonville and Caius; Muir, B.A., King's; P. K. Nix, B.A., Pembroke; Ormerod, B.A., Trinity; Parker, B.A., Gonville and Caius; Pentreath, B.A., Queen's; E. Ransome, B.A., Clare; Ransome, B.A., Gonville and Caius; J. A. K. Renshaw, B.A., Trinity; A. Rotherham, Trinity; Sing, B.A., Christ's; Sladen, M.A., Gonville and Caius; K. S. Storrs, B.A., Emmanuel; Sturrock, B.A., Gonville and Caius; Swarder, B.A., King's; C. A. H. Thomson, B.A., Christ's; Verdon, B.A., Jesus; Watson, B.A., Trinity; Woodhouse, B.A., King's.

At a congregation last week the following degrees were conferred:—

M.D.—Robert B. Ferguson, Gonville and Caius.

M.B. and B.Ch.—John Nachbar, Clare; Howard Marshall, Gonville and Caius; Joshua J. Taylor, Emmanuel; Charles S. Boud, non-collegiate.

The next congregation at which degrees will be conferred will be held on Thursday, May 9th, at 2 P.M.

DURHAM UNIVERSITY.—The following degrees were conferred at a Convocation held on April 27th:—

M.D. (practitioners).—William Percy Ashe, Edward Ferrand, Stanford Harris, Benjamin Jones, Henry Arthur Latimer, William Moxon, John Taylor, Ebenezer Stanley Smith, and Thomas Frederic Young.
M.D. (examination).—George Henry Vane Appleby, Francis William Fullerton, Reginald Green, Walter William Hodgins, William Harvey Mallow, Francis Herbert Marson, and Bernard Bealy Thorne-Thorne.

D.Hyg.—William Henry Turnbull.

M.Sc.—William Martin.

M.B.—Charles Allen Brough, James Atkin Heaton White, John Ralph Prior, Edward Turner, Sidney Herbert Hanley, Harold Dickinson Senior, Norman Bennett, Robert Montagu Le Haute Cooper, William L'Anson Charlton, Percival Davidson, Edward Fielden, Frank Chubb Ford, Ernest Rowland Fothergill, Ernest Edward Frazer, John Reginald Fuller, Richard Withers Gilmour, Gilbert Gocher, Charles Hanks, Ernest Robert Kendall, Wilfrid Robert Kingdom, George Edwyn Middlemist, Marcus Sinclair Paterson, William Harland Peake, Tom Sanderson, Ernest Percy Satchell, and Ernest William Scott.

B.Sc.—Norman Bennett, William L'Anson Charlton, Robert Montagu Le Haute Cooper, Percival Davidson, Edward Fielden, Ernest Rowland Fothergill, Ernest Edward Frazer, John Reginald Fuller, Richard Withers Gilmour, Gilbert Gocher, Charles Hanks, Marcus Sinclair Paterson, William Harland Peake, John Ralph Prior, Tom Sanderson, Ernest Percy Satchell, George William Scott, Edward Turner, and James Atkin Heaton White.

B.Hyg.—George John Auburn, George Henry Vane Appleby, Edward Turner, and Edward Cecil Willcox.

B.Sc.—Robert Beattie.

Dip. P.H.—William Henry Symons.

UNIVERSITY OF ABERDEEN.—The following gentlemen have been admitted to the degrees of M.B. and C.M.:—

B. A. Anderson, J. F. Christie, W. Cockburn, R. L. Collings, H. W. A. Cowan, J. Cran, J. M. P. Crombie, H. W. Cruikshank, T. D. Cumming, C. H. Dyer, A. Fenton, G. W. R. Fernando, J. Fletcher, H. R. Gardner, K. Gillies, W. G. Grant, H. M. W. Gray, D. V. Haig, P. Harper, L. J. Helmrich, G. Hunt, G. H. Johnston, V. V. Langenberg, W. Lethbridge, R. Lindsay, A. H. Lister, M. MacBean, J. R. Macmahon, W. R. Matthews, J. Moncur, A. Mowat, W. Murray, J. W. Myers, E. M. Payne, W. M. Philip, P. Prebble, A. Robb, A. Rose, J. E. Skinner, H. B. Smith, F. J. Troughton, W. S. O. Waring, J. S. Warrack, and A. Wood.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April sittings of the examiners the following candidates passed the respective examinations:—

First Examination (Five Years' Course).—James Moffat Invernarity, Dundee; Alexander J. Wilson, Newnains; William Carey, Haywood; William McFarlane, Cambusnethan; Ewen Mackenzie, Ross-shire; William Denness, Bothwell; T. R. W. Atkins, Cork (with distinction); Owen Felix McCarthy, Cork; Benjamin Bird, Woodford; James Roche, Cork; Henry Fowler, London; William Hutton, Belfast; Harry G. Ogilvie, Jamaica; John Dick, Greenock; and Jeannette Elizabeth Hackett, Westmeath.

First Examination (Four Years' Course).—Lloyd Thomas Lavan, Jersey; Hugh Owen Jones, Llangollen (with distinction); Charles

Frederick Spinkes, Cheshire; Griffiths L. Jones, Carnarvonshire; John Coulter Warwick, Belfast; Robert Henry Munro, Coatbridge; Samuel H. Smith, Alderley; John J. Donagher, Limerick; Reginald C. M. Hoare, Birmingham; John J. Porter, Belfast; Alexander B. Hood, Glasgow; John Wm. Duncan, Newcastle; Robert Cooper, Newcastle; Bryan Jos. Nolan, Tralee; Michael Sheehy, Skibbereen; Andrew S. Omond, Edinburgh; and Andrew H. Jones, Newport (Mon.).

Second Examination (Four Years' Course).—William Haslam Brooks, Farnworth; John E. Harburn, Whitby; John Dunlop, Neilston; Christopher Wm. Davidson, London (with distinction); Edmund Joseph Cummins, Tipperary; William Scott, India; Joseph Sanderson, Yorkshire; Charles Delacherois, Antrim; John Roche, Cork; James Wilson M'Bearty, New Zealand; Richard Fox, Nottinghamshire.

Second Examination (Five Years' Course).—Richard N. Woodley, county Cork; William Mason, Belper; Basil Stanley Sanders, Basaleg, Mon.; Arthur Frederic Seacombe, Cheshire.

Final Examination (and admitted Licentiate).—Francis Thomas Rhodes, Glossop; Lilian May Blake, London; William Austin Mushe, Glasgow; Charles Albert Bois, Glasgow; Patrick Joseph Murphy, Carnbach, Aberdare; William Gordon, Salisbury; James Taylor Hancock, Grimsby; John Livingstone, Glasgow; David Lauder Lindsay, Derby; Alexander Smith, Leeds; Frank John Whitehead, Leicester; Alfred Bernard Steward, Manchester; Duncan Fletcher, Glasgow; John Atkinson, Crewe; Thomas Boulton, Bolton; James W. Astley Cooper, Norfolk; John A. E. A. Lavery, Coventry; Jeanie G. R. Duggan, Edinburgh; Arthur Thompson Hill, Llanrwst; Henry C. Lambart, M.A., Gwynfyll, North Wales; James Cook Neale, Moseley, Birmingham; Bernard H. Woodyatt, Over, Cheshire.

A CONVERSAZIONE will be given by the Medical Society of London on Monday, May 20th, at the rooms of the Society, 11, Chandos-street, Cavendish-square. Mr. A. Pearce Gould will deliver the oration, taking for his subject "The Recent Evolution of Surgery." Subsequently there will be a reception by the President and music by the "Bijou" orchestra.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—

A meeting of this society was held on April 17th, Dr. J. S. Tew, President, being in the chair.—Dr. W. B. Ransom read a paper on Pernicious Anæmia. He based his remarks on a series of twelve cases, six of which ended fatally, and in which microscopical examination of the tissues was carried out. He found in some an increased deposit of iron in the livers and kidneys, but in others there was no increase of iron found in the livers. In some the primary change appeared to be in the blood-forming organs, so that it is an open question whether increased hæmolytic will account for the symptoms or explain the pathology in all cases.—Dr. Cattle detailed a case of pernicious anæmia which had ended fatally, and in this an increase of iron was found in the liver. Drs. Tew, Hunter, and Watson also spoke on the subject.—Mr. Belcher showed the body of a child which had lived for four days whose Abdominal Viscera were Misplaced, being extruded from the abdominal cavity through a small aperture at the umbilicus.

SAMARITAN HOSPITAL FOR WOMEN, MONTREAL.—

A Canadian correspondent writes: "A new hospital for women, with the above name, was opened by Her Excellency the Countess of Aberdeen, wife of the Governor General of Canada, on Jan. 17th, 1895. It is non-sectarian, and is supported entirely by voluntary contributions, of which latter enough were handed in during the first month to carry on the work during a whole year. It is the only special hospital for diseases of women in Montreal, and will be moulded on the pattern of the New York State Women's Hospital in New York city. It is managed by a board of thirty of the principal ladies of the city, assisted by an advisory board of three laymen and three physicians. The staff consists of Sir James Grant, M.D., K.C.M.G., consulting physician; W. H. Hingston, M.D., L.L.D., consulting surgeon; A. Laphorn Smith, B.A., M.D., M.R.C.S. Eng., surgeon-in-chief; H. Lionel Reddy, C.M., M.D., surgeon; S. F. Wilson, C.M., M.D., assistant surgeon and registrar; Dr. Sylvester, assistant surgeon; and Dr. Letellier de St. Just, assistant surgeon. An anæsthetist and a pathologist will be appointed shortly. The out-door service is attended to by the assistant surgeons from 4 to 5 P.M. every day, at which hour the surgeon-in-chief makes his daily visit, and the most urgent cases are admitted. The hospital is absolutely free to women who are poor and sick, and who are residents of the city. Patients from outside the city will be admitted on payment of a nominal charge. The operation days are Thursdays and Fridays at 10.30 A.M., when physicians who have not been attending infectious diseases receive a hearty welcome. The hospital is situated in the choicest and healthiest part of the city, 1000 Dorchester-street, near Mackay-street."

ST. JOHN AMBULANCE ASSOCIATION.—Lord Knutsford, G.C.M.G., has been appointed by His Royal Highness the Prince of Wales director and chairman of the St. John Ambulance Association in succession to Lord Sandhurst, G.C.B., G.C.S.I., the new governor of Bombay.

MEDICAL MAYORS.—Mr. Wm. F. Prichard Bassett, M.D. Edin., M.R.C.S. Eng., has been elected Mayor of Bathurst New South Wales. Mr. John B. Meredith, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been re-elected Mayor of Raymond Terrace, New South Wales.

The following members of the medical profession have been selected for admission to the Order of St. John of Jerusalem in England or for enrolment as Honorary Associates of the Order:—*Knight of Grace*: William Bevil Thorne M.D. *Honorary Associates*: Professor William R. Smith, M.D.; Walter Edward Hacon, L.R.C.P. Lond. (New Zealand); James E. Neild, M.D. (Melbourne); Charles Cotton, M.R.C.P. Edin.; Andrew Clark, F.R.C.S.; Arthur T. Norton, F.R.C.S.; and Charles Fox Goode, M.R.C.S.

RENEWED RISKS OF CHOLERA IMPORTATION INTO ENGLAND.—In several instances vessels have recently arrived in English ports having some cholera history. They have sailed from South American ports, where cholera is now prevalent, and one case at least has proved fatal during the voyage. But in no instance has the ship been deemed to be infected on arrival, and precautionary measures, such as cleansing and disinfection, have alone been necessary. A death from alleged cholera occurred last week at Carlisle, the attack occurring in a man recently arrived from the neighbourhood of the Tyne. The disease is stated to have been clinically cholera; but in the absence of a post-mortem examination such material as was forwarded to the Local Government Board for bacteriological investigation did not suffice to determine the actual nature of the attack.

NORTH-WEST LONDON CLINICAL SOCIETY.—A meeting of this society was held on April 17th, Mr. F. Durham being in the chair.—Mr. Jackson Clarke showed a case of Talipes Equino-varus on which he had operated with success. He detailed the steps of the operation. Mr. Battle advocated manipulation succeeded by fixation in plaster of Paris instead of operation when the children were seen early. Dr. Harry Campbell and Dr. Cagney discussed the possible causes of the deformity to be found in germinal defect.—Mr. Battle read the notes of three cases in which he had operated for Thrombosis of the Lateral Sinus secondary to Middle-ear Disease, and dwelt on the necessity of an early diagnosis. Mr. Jackson Clarke concurred.—Dr. Cagney showed a case of Nephritis with Dropsy, but without Albuminuria, in a child two years old, and described it as a rare condition. Dr. Leatham and Dr. Harry Campbell commented on the case.—Mr. Durham showed a case of Spina Bifida in the Lumbar Region, with Sphincter Paralysis from implication of the Sacral Nerves. Mr. Jackson Clarke and Mr. Battle commented on the case.—Dr. Harry Campbell showed a case of greatly Dilated Heart with Præcordial Bulging and Dyspnoea. He commented on the absence of ascites.

THE FRENCH HOSPITAL AND DISPENSARY.—On Saturday evening last the twenty-seventh annual dinner in aid of the funds of this institution took place at the Whitehall Rooms of the Hotel Metropole, the French Ambassador (Baron de Courcel) in the chair, supported by Sir Stuart Knill as representing the Lord Mayor, and the Italian Ambassador (General Ferrero) and other members of the *corps diplomatique*. After the usual toasts to the Queen and the President of the French Republic the Chairman proposed the customary toast to "The Founders and Benefactors of the Hospital," alluding in pathetic terms to the loss they had sustained in the person of M. Waddington, his predecessor, and coupling therewith the name of Dr. Vintras, who, with the late M. Rimmel, was largely instrumental in founding the hospital and in bringing it to its present state of efficiency. Later in the evening it was announced that subscriptions and donations had been promised to the amount of £2600, including a donation of £25 from the French Ambassador. During the evening vocal and instrumental music was dispensed under the direction of Cavaliere Tito Mattei who, as in years past, kindly gave his services on this occasion in association with Miss Rose Cavendish, Miss Rose Green, and Signor Maggi.

A LEGACY of £50 has been bequeathed to the Metropolitan Hospital Sunday Fund by the late Mr. Crosby Lockwood of Highbury New Park.

We are pleased to hear that the Emperor of Japan has conferred the third-class decoration of the Order of the Rising Sun on Mr. W. Anderson, surgeon to St. Thomas's Hospital. It is well known that Mr. Anderson was for some years resident in Japan, where he collected material for his work on the pictorial arts of that country, which has done much to bring the Japanese favourably under the notice of European art circles.

PRESENTATIONS.—Mr. Frederic E. Peake, L.R.C.P. Lond., M.R.C.S., of Bristol, has been presented by the Emmanuel Ambulance Class with a silver-mounted ebony walking-stick, suitably engraved, in appreciation of his instructive lectures on first aid.—Dr. A. W. Hinsley Walker of Harrogate has been the recipient from the ambulance class in connexion with the Wesleyan Mutual Improvement Society of a handsome electro-plated tea service of fluted pattern and gold-lined, for his professional services as instructor on ambulance aid. This was the third presentation to him for his successful conduct of the class.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Forest-gate Schools.

In anticipation of the Civil Service Estimates Sir John Gorst has given notice of his intention "to call attention to the removal of certain subordinate officers of the Forest-gate schools for having made statements as to the unwholesome food supplied to the children, and to the action of the Local Government Board in relation thereto, and to move a resolution."

Factories and Workshops Bill.

A large number of amendments to this Bill have been prepared in view of the proceedings before the Grand Committee on Trade. Mr. William Allen proposes that the places where work given out by factories and workshops is done should be licensed and subjected to inspection to see that they are not injurious or dangerous to the health of the people employed. Several members have amendments with reference to the temperature of factories and workshops. Sir John Gorst proposes that the age limit for the employment of children should be raised from eleven to twelve years; Mr. John Burns proposes thirteen years, and Mr. MacGregor, L.R.C.P. & S. Edin. &c., fourteen years. Several amendments have also been prepared with regard to the employment of women before and after childbirth. The amendment of Mr. John Burns is to the effect that the occupier of a factory or workshop shall not allow a woman to be employed within eight weeks of childbirth and within six months after she has given birth to a child. Mr. MacGregor suggests an amendment to this making the period prior to the birth of the child three months and the period subsequent also three months.

The Opium Commission Report.

Several members of the House of Commons have given notice of their purpose to call attention to the report of the Opium Commission.

HOUSE OF LORDS.

TUESDAY, APRIL 30TH.

Registration of Midwives.

Lord Balfour brought in a Bill for the Registration of Midwives. The Bill was read a first time.

HOUSE OF COMMONS.

THURSDAY, APRIL 25TH.

Surgeon-Major-General Giraud.

Mr. Campbell-Bannerman, replying to a question put by Sir Albert Rolit, said that the services of Surgeon-Major-General Giraud, Principal Medical Officer at Netley, had not been extended beyond the maximum age laid down by regulation for retirement. The age laid down by the Royal Warrant for retirement of a Surgeon-Major-General was sixty-two, when the interests of the public service would be materially advanced by his retention to that age, and it was deemed advisable to retain Surgeon-Major-General Giraud's services at Netley till he reached that age. He was verbally informed of this at the time it was so decided.

Provision for Old Age.

Mr. Shaw-Lefevre, President of the Local Government Board, answering a question put by Mr. Chamberlain, said that the reports of the Royal Commission on the Provision for Old Age showed very great difference of opinion among its members. It appeared, however, that a majority of them, in their separate reports or memoranda, were of opinion that further examination should be made of the various schemes for old age pensions, with the object of ascertaining whether the difficulties and objections which had been raised to them could be

removed. In view of this the Government would take measures for a further examination of the matter, but they were not at present able to come to any final decision on the subject.

County Government in Scotland.

Sir George Trevelyan, Secretary for Scotland, introduced to the House and explained in outline a Bill to make future provision for local government in the counties of Scotland. Among other public health clauses, he said, there was one which gave to the county council the power to make by-laws with regard to the sanitary arrangements of new buildings. The execution, he explained, would be committed to the district committee, who was the health authority on the spot and in practical exercise of health administration. In another part of his speech he said the medical officers had done good service by their reports to the county councils; but there was great difficulty in getting statistics with regard to births and deaths and the cause of death, such information being the very ABC of a real statistical system. The information had hitherto been got by a voluntary arrangement, but in the Bill it was proposed to give the medical authorities of the counties a legal title to obtain it. Later in his speech Sir George Trevelyan said that attention had been called to the difficulty of providing against the communication of disease by milk cans owing to their being washed with affected water. In the county he knew very well there were no less than 100 persons attacked with typhoid fever, and twenty died through the washing of the cans of a single dairy, which had a large *clintib* with affected water. The Government proposed to give the very strongest power to prohibit, under very severe and rapidly recovered penalties, the sale of milk from any dairy where infectious disease existed. They went further than the English Act of 1890. In that Act it was stated that the powers could only be put in force when infectious disease was caused by the consumption of milk. In this Bill they had added the words "or is likely to arise from the consumption of milk."

FRIDAY, APRIL 26TH.

The Local Government Board and Influenza.

Sir Walter Foster, in reply to Mr. Aird, said that the Local Government Board had instituted more than one inquiry as to the cause of influenza, and the results of these inquiries were contained in reports which had been presented to Parliament. In dealing with this matter, the Board had availed themselves of aid outside their own medical staff. The subject continued to receive the attention of the Board, and at the present time they were employing outside aid in the study of the pathological and bacteriological relations of feverish cold (the so-called "influenza cold") with influenza proper. Information was from time to time received from other countries respecting influenza, and an opportunity was thus afforded for a comparison, in reference to this disease, of administrative measures of various kinds.

MONDAY, APRIL 29TH.

Small-pox Hospital for Bradford.

Mr. Shaw-Lefevre, replying to Mr. Byles, said that the Local Government Board had lately sanctioned a loan to enable the corporation of Bradford to purchase the Bierley Hall estate and some adjoining land as a site for a small-pox hospital. He was aware that the site was outside the borough and that the proposal of the corporation was opposed by persons in the neighbourhood and by the North Bierley Urban District Council. After the local inquiry which was held by one of the Board's medical inspectors as to the purchase of the Bierley Hall estate, the Board pointed out to the corporation certain objections to the erection of a small-pox hospital on this site. The corporation thereupon undertook to purchase additional land adjoining the estate and to change the position of the building. The objections of the Board were thus removed. The Board's medical officer had recommended that no small-pox hospital should be established within a quarter of a mile of a population of 150 or 200 persons. Evidence had been laid before the Board showing that this condition would not be infringed here, and the loan had been sanctioned on the understanding that there would be no such infringement. The reports of the Board's inspectors in cases of this kind were intended for the information of the Board only and were treated as confidential documents.

Poor-law Schools in West London.

Mr. Shaw-Lefevre, in answer to Mr. Fisher, said that the guardians of the Fulham Union had represented to the Local Government Board the inconvenience to which they were put owing to the insufficiency of the school accommodation in the West London school district; but the Board had not felt able to press the managers of the school district to provide further accommodation pending the report of the Departmental Committee which was now considering the subject of Poor-law schools. The Board had, however, instructed the inspector of the district to visit the Fulham Workhouse and ascertain the existing state of things as regards the children there, and afterwards to confer with the guardians with a view of steps being taken to meet the present difficulty.

TUESDAY, APRIL 30TH.

Disease in American Sheep.

Mr. Herbert Gardner replied at some length to a question on this subject put to him by Sir Herbert Maxwell. He said that after examination of the specimens sent to the Board of Agriculture, the veterinary officers of the Board had come to the conclusion that the disease was one of a parasitic nature well known to American pathologists, and fully described by them under the title of Nodular Disease of the Intestines. The subject, he went on to say, would continue to engage the attention of the Board, but it was not one which he thought need cause much anxiety to stockowners in this country. Large numbers of sheep had been imported from the United States, but so far as the veterinary officers were aware the particular parasite in question had never been detected in home animals, although the disease had been well known to exist in the South-eastern States for many years past.

Cholera and Filters.

Mr. Brookfield asked the Secretary of State for War whether an outbreak of cholera affecting several companies of the East Lancashire Regiment at Lucknow had been traced to the barrack-room filter; whether his attention had been called to the examination by Dr. Sims Woodhead and Dr. Cartwright Wood, at the Research Laboratory of the College of Physicians and Surgeons, of filters used in the Home Army,

and to their conclusion that such filters were not only useless against disease, but probably materially increased the risk; whether he was aware that, as the consequence of applying to over 200,000 quarters a special system of filtration, the French War Office found that wherever the system was introduced typhoid fever disappeared, and that as its introduction extended the number of cases continuously decreased, showing according to the last report less than one-half of the average before the introduction of the system in 1888; whether he could say what special kind of filter was used in the system adopted by the French War Office; and whether he was aware that the number of cases of typhoid fever per thousand was 60 per cent. higher in the British Army in 1893 than in the French Army.

Mr. Woodall replied: Yes, sir; there was an outbreak of cholera at Lucknow last year. The Government of India appointed a special committee to inquire into the cause, and the report has not yet been issued. It appears, however, that it was due to a contaminated filter and filter bed in the barracks. The report by Dr. Woodhead and Dr. Wood, which the hon. member refers to, was one made last year to the British Medical Association on the relative efficiency of filters in general, and though very interesting and instructive it presents no new facts, but confirms the already existing opinion that the ordinary filters so largely used in the barracks in India are not effectual for the perfect purification of water unless it is previously boiled. Two hundred thousand of the "Chamberland-Pasteur" filter have been supplied to French barracks, hospitals, and laboratories, and it has been estimated that the deaths from enteric fever are 60 per cent. lower in 1892 than in 1886-7 and the cases 60 per cent. fewer.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on the subject of Food Products Adulteration, of which Sir Walter Foster is chairman, resumed its inquiry on Tuesday, April 30th.

The first witness examined was Mr. T. P. Ling, who appeared as a representative of the Trade Section of the London Chamber of Commerce. He had considerable experience in the retail trade in butter and margarine, and he was emphatically of opinion that margarine should not be packed in baskets or other packages with detachable labels. He would not stop the sale of margarine mixtures, because it would be unfair to the public, who were very fond of them; but he would insist on them being sold as mixtures. As to prosecutions, he thought that in every case the assistant who actually sold the article should be summoned as well as the principal. If that were done the assistants would refuse to sell fraudulent articles. As to imprisonment being imposed, all he as a large employer could say was that he would soon cease selling margarine if he were liable to imprisonment. His suggestion was that there should, in addition to the vestries, be a central authority, such as Scotland Yard, to which any member of the public might go and demand as a right that samples should be taken in a particular shop. He would require of a person who made this demand that he place a deposit of £5 in order to prevent frivolous proceedings. The present system of inspection lent itself to bribery, and in his opinion bribery prevailed to a considerable extent, although he was not prepared to offer proof of it.

Mr. J. R. Webb, a representative of the Provision Trade Section of the London Chamber of Commerce and the Cheese Sub-committee of the Home and Foreign Produce Exchange, said he had given special attention to the evils arising from the importation of adulterated cheese. A few years ago it was the boast of the trade that cheese was one of the few articles of food not adulterated, but that boast could no longer be made, because a large trade in what was called imitation or filled cheese had sprung up within the last few years. Large quantities of this imitation cheese came from America, from Hamburg, and from Holland. It was made from skimmed milk, and in order to disguise the poverty of the article there was an addition in some of it of lard and in some of oleo. The result was not a cheese, not even an inferior cheese, although it was sold as a genuine full-cream cheese. If this article were kept a little time it went bad, and the mere process of rubbing it between the finger and thumb was sufficient to separate the foreign fat from the curd. Asked why, if the adulteration were so easily detected, the large trade in this article continued, witness said that the profits were so enormous that traders were prepared to run the risk. In Canada and many of the States of America laws had been passed prohibiting the manufacture of filled cheese. As to the remedy for this state of things, he recommended greater activity on the part of the Customs authorities and a law prohibiting both the importation and the manufacture of the article. He would give the Customs authorities power to stop consignments at the port of entry, and have analyses made, and he would also give powers to seize the article when found in warehouses. In his opinion this imitation cheese was an unwholesome article of food. If young it was very indigestible, and if kept till old it was rancid and offensive.

Mr. Cecil Rowson, representing the Liverpool Provision Trade Association, gave evidence as to the large quantity of filled cheese imported into Liverpool from America, and the prosecutions which have taken place in connexion with its sale. He said that only an expert could distinguish it from genuine cheese, although it had scarcely any of the nutritive properties of that article. He contended that both its manufacture and its importation should be prohibited by law.

The Committee then adjourned.

The Committee met again on the following day, with Sir Walter Foster in the chair.

Mr. William George Watson, a member of the firm trading under the style of the Maypole Dairy Company, examined by the Chairman, said that they had about sixty retail shops in Scotland, the north of England, the Midlands, and Ireland, and were perhaps the largest retailers of margarine in Great Britain. They had eight creameries in Ireland and one in England, and butter-buying offices in Denmark and Holland. When they engaged their assistants they got them to sign an undertaking to observe the requirements and provisions of the Margarine Act of 1887 and to indemnify the firm against damages, fines, &c., occasioned by any neglect or irregularity on their part in connexion with the sale or exposure for sale of margarine. On the back of the undertaking there were printed the provisions of the Margarine Act. In spite of these precautions the firm had been prosecuted. In purchasing margarine 90 per cent. of their customers asked for fivepenny, sixpenny, or sevenpenny, as the price might be

8 per cent. asked for butter, and only 2 per cent. actually asked for margarine. They all knew perfectly well that it was margarine they wanted and were getting, but they avoided naming it. He wished to see all margarine wrapped in paper with nothing else marked upon it save the word "Margarine," and to meet the objection on the part of customers to going about with it thus exposed he would allow an outer cover. Then he would have the assistant who sold the article prosecuted as well as the principal, and he would also like to see a central department to which complaints as to adulterations might be made. Otherwise he thought the present Margarine Act, properly enforced, was a sufficient protection to the public. He saw no objection to margarine being coloured to suit the taste of the consumer, or to its being kept in special receptacles. As to water in butter, his firm found during the excessive heat in 1893 that the butter from one of their creameries in Ireland contained 22 per cent. of water. They expressed surprise at this, and ordered another analysis, but with practically the same result. Thereupon they sank artesian wells and got refrigerators, and in this way reduced the percentage. In salting the butter they used dry salt and not brine. He accounted for the higher percentage in Irish butter compared with butter made in Denmark by the fact that in the latter country they had an ample supply of ice, which enabled them to get the water out of the butter.

By Mr. Colman: He was against imprisonment for offenders under the Margarine Act, because a principal might be sent to prison for an act of his assistant done in defiance of his instructions. The opinion he held about margarine was that pure margarine was far superior to poor butter.

By Mr. Frye: The false reports circulated about the constituent parts of margarine did great harm to the trade, and had led many people to believe that all manner of rubbish went to the making of the article.

By Mr. Kilbride: There were towns in Lancashire where the people insisted on having butter almost as white as lard. He denied that the effect of colouring margarine was to make it resemble butter as much as possible. In Denmark the customer bought his margarine uncoloured, but he took home with him capsules for the purpose of colouring it according to his taste.

The Committee then adjourned for a week.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

- BIRD, R. K., L.R.C.P., L.M., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator for Natimuk, Victoria, Australia, vice Weber, resigned.
- BRYDEN, F. W. A., M.R.C.S., has been appointed Honorary Medical Officer to the Royal Surrey County Hospital, Guildford.
- COOPER, C. E., M.B., B.C. Cantab., has been appointed House Physician to the City of London Hospital for Diseases of the Chest, Victoria-park.
- DANIEL, W. P. TAYLOR, L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed Medical Officer of Health for the Farnley Tyas Urban Sanitary District, vice Shaw, resigned.
- EDWARDS, E. C., M.B., C.M. Edin., has been appointed Senior House Surgeon to the East Suffolk Hospital, Ipswich.
- FYFE, E. H., M.B., Ch.M. Glasg., has been appointed a Public Vaccinator for Fitzroy, Victoria, Australia.
- GEMMELL, JOHN E., M.B., C.M. Edin., has been appointed Hon. Hospital Medical Officer to the Ladies' Charity and Lying-in Hospital, Liverpool.
- GRINDSALK, T. B., M.B., M.R.C.S., has been appointed Hon. Hospital Medical Officer to the Ladies' Charity and Lying-in Hospital, Liverpool.
- HAIN-BROWN, C. WM., M.B., M.S. Alder., M.R.C.S., has been appointed Honorary Medical Officer to the Royal Surrey County Hospital, Guildford.
- HARRISON, J. W., M.B., Ch.M. Melb., has been appointed a Public Vaccinator for Shepparton, Victoria, Australia, vice Hughton, resigned.
- HINES, G. J., L.R.C.S., L.M. Irel., has been appointed Medical Officer for the No. 4 Sanitary District of the Hollingbourn Union.
- HOGG, G. H., M.B., Ch.B. Edin., has been appointed Government Medical Officer and Vaccinator for the District of Cooma, New South Wales, vice Clifford, resigned.

JACOB, E. L., M.R.C.S., has been appointed Medical Officer of Health for the Leatherhead Urban Sanitary District.

JACOBIEN, G. O., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Pembroke Sanitary District of the Kingston Union.

KIERNSMEIER, H. B., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer to the Narrandera Hospital, New South Wales.

MACGREGOR, J. J., M.D. Lond., F.R.C.S., M., L.R.C.P., has been appointed Assistant Surgeon to the Essex and Colchester General Hospital.

MACKENZIE, THOMAS, M.A., M.D. Edin., has been appointed Physician to Noble's Isle of Man General Hospital and Dispensary.

NEWMAN, F. JAS., M.B., Ch.B. Melb., has been appointed Health Officer for the Shire of Barrabool, Victoria, Australia.

NICHOLSON, B. H., M.B., M.S. Edin., has been appointed Assistant Surgeon to the Essex and Colchester Hospital.

O'DONNELL, J., M.B., B.Ch. Irel., has been appointed Medical Officer to the Dublin Metropolitan Police Medical Aid Association.

PAYNE, HENRY, M.D., M.R.C.S., L.S.A., has been appointed one of the Honorary Medical Officers to the Ashton-under-Lyne District Infirmary.

POLAND, J., F.R.C.S., M., L.R.C.P. Lond., has been appointed Surgeon to the City Orthopaedic Hospital, vice Chance.

BENNIE, G. E., M.D. Lond., M.R.C.S., has been appointed Government Pathologist for the Metropolitan District of Sydney, New South Wales.

RICHARDS, J. B. O., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Milton Abbot Sanitary District of the Tavistock Union.

ROBINSON, T. H., M.D., Ch.M. Edin., has been appointed Surgeon-Captain to the Western Australian Defence Forces.

RUSSELL, F. R., M.D. Edin., M.S., has been appointed Honorary Medical Officer to the Royal Surrey County Hospital, Guildford.

SCOTT, J. M., M.B. Melb., has been appointed a Public Vaccinator for Steiglitz, Victoria, Australia, vice Spred.

SHEWIN, ALFRED, M.D. Lond., M.R.C.S., has been appointed Honorary Consulting Physician to the Prince Alfred Hospital, New South Wales.

SHUTTER, R. E., M.B., Ch.B. Melb., has been appointed, *pro tem*, a Public Vaccinator for Bendigo, Victoria, Australia.

SMITH, J., L.R.C.P., L.R.C.S. Edin., has been appointed Health Officer, and Medical Officer to the Police and Gaols at West Devonport, Tasmania, vice Richardson, resigned.

STANTON, THOMAS, M.B. Dubl., L.R.C.S., L.M. Irel., has been appointed a Public Vaccinator for Kororo, Victoria, Australia, vice Jernyn, resigned.

THOMAS, J. LYNN, F.R.C.S., has been appointed Assistant Surgeon to the Cardiff Infirmary.

THORNE, J. M., L.R.C.P. Lond., M.R.C.S., has been appointed Consulting Surgeon to the Retford Cottage Hospital.

WILLOUGHBY, A. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Sunbury Sanitary District of the Staines Union.

YEATES, EDWARD, L.R.C.P. Irel., L.M., L.R.C.S., has been appointed a Public Vaccinator for Learmouth, Victoria, Australia, vice Salter, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ADDENBROOKE'S HOSPITAL, Cambridge.—Resident House Physician. Salary £25 per annum, with board, lodging, and washing in the hospital.

ASYLUM FOR IDIOTS, Earlswood, Redhill, Surrey.—Assistant Medical Officer. Salary £150 a year, with board and residence. Applications to the Secretary, 36, King William-street, London-bridge, E.C.

BOROUGH OF STOCKTON-ON-TES.—Medical Officer of Health and Medical Superintendent of the Fever Hospital. Salary £500 per annum. Applications to the Town Clerk.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's-inn-road.—Clinical Assistants.

DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

EAST LONDON HOSPITAL FOR CHILDREN, Glams-road, Shadwell, E.—House Surgeon. Board, lodging, &c., provided.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glams-road, Shadwell, E.—Assistant Physician for Out-patients.

EAST SUFFOLK AND IPSWICH HOSPITAL, Ipswich.—Second House Surgeon, unmarried. Salary £70 per annum, with board, lodging, and washing.

GENERAL HOSPITAL, Nottingham.—Assistant House Surgeon, for six months. Board, lodging, and washing in the hospital provided. Also Assistant House Physician, for six months. Board, lodging, and washing in the hospital provided.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS, 32, Soho-square, London, W.—Resident Medical Officer, for six months. Board, residence, and washing provided, and a honorarium of £10 10s. given.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Physician to Out-patients. Applications to the Secretary, Offices, 27, Clement's-lane, E.C.

PARISH OF ST. MATTHEW, BETHNAL-GREEN.—Junior Assistant Medical Officer for the Workhouse, Waterloo-road, E., for six months. Honorarium of £20 will be given, with rations, furnished apartments, and washing. Applications to the Clerk, Guardians' Offices, Bishop's-road, E.

RUTHURHAM HOSPITAL AND DISPENSARY.—Resident House Surgeon for three years. Salary £100 per annum, with rooms, washing, and commons (exclusive of alcoholic drinks).

SCHOOL BOARD FOR LONDON.—Medical Officer for the Board's Truant School, Upton House, Homerton. Salary £100 per annum. Applications to the Clerk of the Managers, School Board Offices, Victoria Embankment, W.C.

SMEDLEY'S HYDROPATHIC ESTABLISHMENT, Matlock.—Junior Physician. Honorarium of £40 for first six months, and afterwards at the rate of £120 per annum, with board, lodging, &c.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, Albert Embankment, London, S.E.—Lecturer on Physiology.

THE DENTAL HOSPITAL OF LONDON, Leicester-square, W.C.—Two Dental Surgeons.

THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—House Physician, for six months. Salary at the rate of £70 per annum, with board and lodging.

WESTMINSTER GENERAL DISPENSARY, 9, Gerard-street, Soho, London, W.—Honorary Surgeon.

WEST RIDING ASYLUM, Wadley, near Sheffield.—Fifth Assistant Medical Officer. Salary £100 per annum, rising £10 a year up to £150, with board &c.

WORCESTER GENERAL INFIRMARY.—Assistant House Surgeon and Dispenser, for two years; unmarried. Salary £70 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS.

COLLETT.—On April 26th, at Ivy House, Marske-by-the-Sea, Yorkshire, the wife of H. G. Outram Collett, L.R.C.P. Lond., M.R.C.S. Eng., of a daughter.

ENSOR.—On April 17th, at Windsor-place, Cardiff, the wife of Mr. Henry Colleen Ensor, surgeon, of a son.

JONES.—On April 26th, at Claybury, Woodford, Essex, the wife of Robert Jones, M.D., of a daughter.

MOORE.—On April 23rd, at Clarence House, Staines, the wife of S. J. Moore, M.D., of a daughter.

WATT.—On April 30th, at Millbrook, Plymouth, the wife of J. Leslie Watt, M.B., of a son.

MARRIAGES.

CARR—GRIFFITH.—On April 24th, at the Brixton-hill Wesleyan Church, by Rev. J. H. Rigg, D.D., and Rev. Richard Roberts, John Walter Carr, M.D., M.R.C.P., of 13, Cavendish-place, W., only son of the late John Carr, J.P., and of Mrs. John Carr, of 40, Bloomsbury-square, to Jessie, daughter of Walter Griffith, of Palace-road, Streatham-hill.

DODD—DODD.—On April 25th, at Holy Trinity Church, Tulse-hill, by Rev. S. O. Dodfield, M.A., M.B., Medical Officer of Health, Paddington, of Blomfield-road, Maids-valle, to Elsie, fourth daughter of Arthur Dodd, of Kimberley, Tulse-hill, S.W.

LORD—WILLIAMS.—On April 23rd, at St. James's, Manchester, by the Rev. W. J. Sims, M.A., Robert Ellis Lord, M.D., B.Sc. Lond., of Colwyn Bay, to Elizabeth Margaret, daughter of William Williams, Esq., of Brecon.

MITCHELL—BLACKWELL.—On April 22nd, at St. James's Church, Paddington, by the Rev. R. Mitchell, late vicar of Wild, and the Rev. W. J. Sowter, vicar of Eltham, Ernest J. D. Mitchell, B.A., M.B., B.C., of the Grange, Eltham, to Kate Beatrice, widow of Edmund Alfred Blackwell, and daughter of the late C. F. Clements, of 3, Portchester-square, Hyde-park.

MUMFORD—READ.—On April 25th, at the Free Church, Kentish Town, Alfred Alexander Mumford, M.D., of Chorlton-cum-Hardy, to Edith Emily, second daughter of Charles Read, M.D., of Regent's-park, London.

ORD—PARTRIDGE.—On April 25th, at the Parish Church, Bromley, Kent, Reginald Whistler Ord, M.A., M.R.C.S., L.R.C.P., of Dover, to Mary Coralie, eldest daughter of Henry Partridge, J.P., of Barnfield, Bromley, Kent.

PRINCE—PETTINGER.—On April 23rd, at the Parish Church, Chorlton-cum-Hardy, John Woolnough George Prince, M.R.C.S., L.R.C.P., of Hartfield, Sussex, to Sarah Rose, younger daughter of the late Geo. W. Pettinger, M.R.C.S., Alexandra-park, Manchester.

ROWLAND—HADEN.—On April 24th, at St. George's, Ramsgate, Frank Mortimer Rowland, M.B. Camb., of Lichfield, to Ellen Josephine, second daughter of the late W. H. Haden, of Cardigan.

TELFORD-SMITH—STERRY.—On April 27th, at St. Stephen's Church, South Kensington, by the Rev. A. W. Gros, rector of Milton, Northampton (cousin of the bridegroom), Telford Telford Smith, M.A., M.D., B.Ch., Medical Superintendent, Royal Albert Asylum, Lancaster, eldest son of Thomas Smith, Esq., Eglinton-road, Donnybrook, Dublin, to Ada, only daughter of W. Jex Sterry, of Norwood.

DEATHS.

DENNISTON.—On April 10th, on board R.M.S. *Tongarivo*, James Denniston, M.D., of Bowdon, Cheshire, fifth son of the late Archibald Denniston, W.S., Greenock, N.B., in his 41st year.

GREENHILL.—On April 30th, from an accident whilst riding, Arthur Francis Greenhill, L.R.C.P., M.R.C.S., of The Lawn, Barnes, Surrey, aged 55.

HARRIS.—On April 26th, suddenly, at Denmark-hill, Camberwell, Henry Harris, M.R.C.S., aged 57.

INNES.—On April 23th, at Cairo, Edward Innes, M.B., C.M. Edin., youngest son of the late Sir James M. Innes, of Edingight and Balveny, Bart., aged 30.

JOHNSON.—On April 23th, suddenly, at Aigle, Vaud, John Johnson, M.D., late of Elmstead, Tunbridge Wells.

OSBURN.—On April 29th, at Santa Fe, New Mexico, Henry Walter Osburn, M.D., eldest son of Henry Osburn, Cedars-road, Clapham, late of St. Andrew's, New Brunswick.

TOMKIN.—On April 26th, at Witham, Essex, Thomas Marchant Tomkin, Surgeon, aged 76.

WILKINS.—On April 25th, at Ealing, Henry Wilkins, M.R.C.S. Eng., L.S.A., in his 24th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.), National Hospital for Diseases of the Heart and Paralysis (3 P.M. and 8 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.), National Hospital for Diseases of the Heart and Paralysis (3 P.M.).

Ormond-street (9.30 A.M.), National Hospital for Diseases of the Heart and Paralysis (3 P.M. and 8 P.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.), National Hospital for Diseases of the Heart and Paralysis (3 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), National Hospital for Diseases of the Heart and Paralysis (3 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Mr. F. J. Bennett: The Subject of Dental Caries (with illustrative specimens). Exhibits by Mr. Storor Bennett. Casual Communication by Mr. Oswald Fergus.

WEDNESDAY.—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Mr. H. T. Butlin: (1) Tumour of Neck, with Paralysis of Sympathetic Nerve; (2) Case showing Paralysis of Right Vocal Cord.—Dr. James Donelan: Case of Perforation of the Hard Palate occurring after Influenza in a previously healthy Boy aged twelve; also "sequestrum" from same case.—Mr. Charles A. Parker: Case of Tubercle of the Nose and Pharynx.—Dr. L. H. Pegler: Microscopic Sections illustrating the Histology of Anterior Hypertrophies of the Interior Turbinate body.—Mr. W. R. H. Stewart: Case of Fistula in the Neck.—Mr. Charters Symonds: (1) Polyp from the Antrum, Unusually large Nasal Polypus, Post-nasal Sarcoma (specimens); (2) The case of Pachydermia previously shown.—Dr. Herbert Tilley: Case of Laryngeal Ulceration (?syphilitic or tubercular). Also by Mr. A. A. Bowdly and Dr. Dundas Grant.

THURSDAY.—BRITISH GYNÆCOLOGICAL SOCIETY.—Nomination of Fellows; Ballot. Dr. H. Michie: Pregnancy complicated by Suppuration within the Pelvis (with cases). Specimens by Mr. O'Callaghan, Mr. Bowman Jessett, and Dr. John Shaw.

SOUTH WEST LONDON MEDICAL SOCIETY (Vestry Room, Town Hall, Wandsworth).—8.30 P.M. Dr. Hale White: On the Increase in the Frequency of Eupneuma as a Complication of Pneumonia during the Influenza Epidemic.

FRIDAY.—CLINICAL SOCIETY OF LONDON.—Mr. R. W. Parker: A case of an Infant in whom some of the Abdominal Muscles were absent.—Mr. Arbuthnot Lane: A case of Extensive Degenerating Nævus of the Bladder.—Mr. L. A. Dunn: Two cases of Gastric Ulcer treated by Laparotomy.—Mr. Silcock: Two cases of Perforating Gastric Ulcer—in one Excision of Edges, Suture, Death; in the other Formation of Reparative Adhesions, Laparotomy, Drainage, Recovery.—Dr. F. Lucas Benham: Thickened and Contracted Mesentery simulating Tumour in a case of Cirrhosis of the Liver.—Dr. Sidney Phillips: A case of Splenic Abscess; Secondary Suppuration in the Liver, and Death from Pyæmia.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 1 P.M., Mr. R. M. Gunn: Clinical Examination of the Eye.—London Throat Hospital, Gt. Portland-street, W., 8 P.M., Mr. W. R. H. Stewart: Examination of the Ear.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Percy Smith: Hysterical and Delirious Mania.

WEDNESDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 P.M., Mr. A. Q. Silcock: Choroidal Affections, with illustrative cases.—Hospital for Skin Diseases, Blackfriars, 1 P.M., Dr. Payne: Psoriasis.

THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Mr. Edmund Owen: Cases from the Surgical Ward.—National Hospital for the Paralyzed, Bloomsbury, 2 P.M., Dr. Beccov: Locomotor Ataxia.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. John Hopkins: Cases in the Wards.

FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 4 P.M., Prof. Crookshank: The Microscope and Methods of Cultivation.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Hyslop: Acute Mania.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

TO ADVERTISERS.

THE pressure on our advertisement space this week has necessitated the omission of some few of our clients' announcements.

AN UNORTHODOX REMEDY.

THE scientific mind is often exercised to account for the reason of certain ceremonial remedies of savage and primitive peoples which, while absurd by reason of the manner of their administration, have in them, nevertheless, a substratum of truth. Accident will account for the discovery of the remedy in a great many instances, and the desire for power would induce the "doctor" or medicine man to surround the remedy with an elaborate ritual in order that he might act on the credulity of human nature and minister to its love of mystery. In the *Sunday Magazine* the Rev. S. Baring Gould relates the following story, and, apart from its humour, it is interesting to speculate on the probable outcome of a similar incident in more superstitious times:—

"A poor woman came to the parson of a parish with the request, 'Please, pass'n, my old sow be took cruel bad. I wish now you'd be so good as to come and say a prayer over her.' The parson protested that it would degrade his sacred office, but, the woman being very importunate and beginning to sob, to pacify her he went to the cottage to see the sow. Raising his right hand in a solemn manner, he said, 'If thou livest, O pig! then thou livest; if thou diest, O pig! then thou diest.' Singularly enough the pig recovered. Some time after, the parson falling ill with a quinsy that nearly choked him, the woman went to see him when he was almost in *extremis*, and, raising her hand, she pointed to him with her finger, saying, 'If thou livest, O pass'n, then thou livest; if thou diest, O pass'n! then thou diest.' An explosion of laughter burst the quinsy, and the 'pass'n' recovered."

The story is told in the writer's well-known happy style, but space compels us to condense it, and this necessarily somewhat spoils the humour.

F. W. E.—Yes.

MEDICAL MEN AS PROPRIETORS OF ADVERTISED FOODS IN LIMITED COMPANIES.

A RESPECTED CORRESPONDENT asks our opinion of the propriety of medical men accepting shares or debentures offered primarily to the profession by a leading member of a firm dealing in articles of food or in beverages more or less alcoholic and alleged to have special virtues for invalids. These virtues are advertised on a large scale. In the circular offering the debentures to the profession it is stated as a reason for such offer that the success of one of the principal articles is mainly due to the kind recommendations of the medical faculty. We can have no hesitation as to our reply. Medical men should have no pecuniary interest in foods which it may be their duty to have to prescribe. Not very long ago a number of medical men narrowly escaped the censure of the General Medical Council for accepting foundation shares in such a company on condition of advertising the wares of it. It is true that in the case now under consideration the purchasers of debentures are not required to furnish testimonials of the articles; but they would be in a position in which it would be to their interest more or less, and as members of the company they would be responsible for methods of advertising wares which they might not always approve.

ADVERTISEMENT OF MEDICAL NAMES AT SOUTHPORT.

MEDICAL PRACTITIONERS connected with hospitals and sanatoria at Southport and elsewhere would do a great service by refusing permission for their names to appear in the advertisement of such institutions. We see in the *Southport Visitor* a long list of such advertisements, including the names and qualifications of their medical officers. We recognise that these advertisements are drawn not by them, but by the enterprising secretary or lay officers. But the names are there nevertheless, and give an excuse to those who practise by direct advertisement for saying that those who stand high in the profession do not need to do so, seeing they have advertisement done for them.

MINERAL WATERS AS A BASIS OF MEDICAL ADVERTISING.

A LIST of names and addresses of medical practitioners supports an advertisement of mineral waters, and, we are informed, appears frequently in a Croydon newspaper. We are sure that the gentlemen in question will take steps to prevent the Association in fault from thus using their names to promote a commercial speculation in a manner contrary to the ethics and derogatory to the dignity of the profession.

"PULEX IRRITANS."

To the Editors of THE LANCET.

SIRS,—May I never find myself in a similar plight to Dr. Neale, for I am very susceptible to flea influence. Of late years I have avoided protracted acquaintance with these pests, for I have during the summer months carried a bottle of chloroform, and when bitten have poured a little of the CHCl_3 on my clothes immediately over the spot, which at once soaks through and permanently quiets P.I. and allays the irritation of its bite.

I am, Sirs, yours faithfully,

Canterbury, May 1st, 1895.

W. PUGIN THORNTON.

LLANDRIDOD WELLS COTTAGE HOSPITAL.

MR. J. Morgan Evans.—Rule 11 certainly needs to be made plainer. There is little use in giving medical men the right to "visit" their cases if they are not to be allowed to attend them or to prescribe for them. That this is the natural construction of the word is confirmed by the requirement of legal qualifications in the medical man to whom the privilege is accorded. It may be argued, indeed, that Rule 10 gives full power to the medical director; but this is not so clear. By this rule the medical director is to have entire control over the medical management of the hospital; but this must be construed with reference to Rule 11, which gives power to any medical practitioner to visit his patient—that is, of course, to visit him in a professional sense. Such should be the reading of the rule in an institution of this kind.

LOW FEES FOR EXAMINATION IN LIFE ASSURANCE.

A CORRESPONDENT informs us that he had declined the office of examiner for life assurance for the Order of Foresters on low terms, and was surprised at its acceptance by members of the profession whom he names. We think he was right. We admit that in the case of life assurance in friendly societies for really small sums medical officers should charge lower fees than for ordinary assurance work; but the fees here are too small—5s. for policy of £100; 7s. 6d. for £200; 10s. for £400; 12s. 6d. for £600.

A DOMESTIC CONVENIENCE.

THE Safety Letter Box Co., 14, Sherborne-lane, King William-street, E.C., send us an ingenious circular rim, in mahogany, to be placed on chamber utensils in the nursery. It is called "The 'Relief' Seat for Children."

DANS CETTE GALÈRE.

A CORRESPONDENT sends us a card which was found by the ladies of his household nestling in the price-list of a London tradesman. It is charitable to presume that it got there by accident; but the words in brackets are somewhat suggestive, and certainly unnecessary in the case of those to whom alone the change of address should be indicated—viz., the practitioner's own patients and his private friends. We append a copy of the card, omitting the name and the addresses.

CHANGE OF ADDRESS.

MR. _____,

(Medical Practitioner.)

HAS REMOVED TO

_____ ROAD.

[FIRST HOUSE OUT OF _____ ROAD.]

FROM _____ ROAD.

A M.O.H.—The answer must mainly depend on the source of the instructions received by the medical officer of health to attend the inquiry. As a rule, attendance at such an inquiry at the request of the local sanitary authority for whom the officer acts does not carry a fee with it; but in the case of an officer only giving part-time services we see no reason why he should not claim a fee for such exceptional services. If the county council requested the officer's attendance, then he should claim a fee from them; for the local medical officer of health has no duties towards a county council, except as regards the transmission to them under the Local Government Act, 1888, of certain reports.

Mr. C. Stanley Kirtton.—No.

VACCINATION IN GERMANY AND FRANCE.

To the Editors of THE LANCET.

SIRS,—I shall feel deeply grateful if any of your correspondents can furnish me with information about the vaccination laws in Germany and France. The points which I am most anxious to obtain some knowledge of are—(1) whether there is a public system of vaccination in these countries, and (2) whether the law states anything definite with respect to the number of "marks" to be made.

I am, Sirs, yours faithfully,

Cardiff, April 29th, 1895.

T. GARRET HORDER.

MEDICAL ADVERTISING IN JOHANNESBURG.

'DR. SPEER,' Johannesburg, has a very large advertisement in the *Star* of that place in the true newspaper style: "All skin diseases from whatever cause absolutely cured within a stated time," &c. The Medical Corporations of Great Britain are not responsible for "Dr. Speer's" methods. He boasts of being a graduate of the Medical Department of Harvard University, Class 74. It is for the authorities of that University to consider whether they should take any steps in regard to "Dr. Speer."

MEDICAL ADVERTISING.

WE append a further illustration of this disastrous and discreditable innovation in methods of practice. We omit the name and residence of the practitioner, which, however, appear on the bill.

"The Surgery, 434, Whitehorse-road, Thornton-heath. Hours: Morning, 10.30 to 12; Evening, 7.30 to 9; Sunday, 7 to 8.30 P.M. Fees: Medicine and Advice at Surgery, 1s.; Home Visit, with Medicine, from 1s. 6d.; Midwifery from 15s.; Vaccination, 1s."

THE HACK TUKE MEMORIAL.

AN influential committee is being formed to raise a fund to perpetuate the memory of the late Dr. Hack Tuke by a prize, medal, or other means for the encouragement of the study of psychological medicine. The acting honorary secretary is Dr. Fletcher Beach, 64, Welbeck-street, W.

Just Qualified.—Manual of Practical Morbid Anatomy (Cambridge Natural Science Manuals), by A. A. Kanthack and H. D. Rolleston, Cambridge University Press. H. K. Lewis, 136, Gower-street, W.C. Price 4s. 6d.

During the week marked copies of the following newspapers have been received:—*Sussex Daily News*, *Whitehall Review*, *Bedford Advertiser*, *Liverpool Courier*, *Birmingham Gazette*, *North Eastern Daily Gazette*, *Hastings and St. Leonards News*, *North Wales Chronicle*, *Bridge of Allan Reporter*, *Stirling Saturday Observer*, *Ayr Observer*, *Oldham Standard*, *Ashdon Standard*, *Gloucester Chronicle*, *Courier de la Presse*, *Surrey Advertiser*, *Sutton Coldfield and Erdington Times*, *South London Press*, *Deansbury Reporter*, *Guy's Hospital Gazette*, *Australian Medical Journal*, *Local Government Journal*, *Kerry Sentinel*, *Australasian Medical Gazette*, *Spalding Free Press*, *West Middlesex Advertiser*, *Ilfracombe Gazette*, *Covey Times*, *Buckingham Observer*, *Banffshire Journal*, *Guernsey Star*, *Preston Herald*, *Leamington Spa Courier*, *St. Mary's Hospital Gazette*, *Rochdale Observer*, *North British Daily Mail*, *Irish News Home News*, *Todmorden Advertiser*, *Builder*, *Times of India*, *Architect*, *Citizen*, *Pioneer Mail*, *Manchester Evening Mail*, &c., &c.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

A Clinical Lecture

ON

TWO CASES IN WHICH A DOUBLED SECOND SOUND WAS AUDIBLE ONLY NEAR THE APEX OF THE HEART.

*Delivered at the London Hospital, Nov. 29th, 1894,*By A. ERNEST SANSOM, M.D. LOND.,
F.R.C.P. LOND.,PHYSICIAN TO THE LONDON HOSPITAL AND LECTURER ON CLINICAL
MEDICINE AT THE LONDON HOSPITAL MEDICAL COLLEGE.

GENTLEMEN,—The title of this lecture may cause you to think that I have chosen a subject which is not in the highest degree of practical utility; but I have selected the two cases which are to serve as the groundwork of my observations to-day: first, because they cannot fail, apart from all abstruse questions and undetermined problems, to inculcate some useful lessons; next, because they can tell us much in corroboration of extant teaching; and lastly, because they illustrate some doctrines lately discussed which are not accepted by a majority of observers. We are not the judges of the ultimate practical significance of observed phenomena; let us read the lines which these patients unconsciously write for us carefully and faithfully, and then let us invoke with due judgment the scientific uses of the imagination. I shall give you an outline of the cases with a running commentary.

CASE 1.—A woman aged twenty-one years was admitted on Sept. 6th, 1894, for acute rheumatism. In regard to her family history, her father, aged fifty-three years, is healthy; her mother, aged fifty-two years, is healthy; and her five brothers are healthy. She has three sisters; one, aged thirty-two years, suffers from heart trouble, and one, aged twenty-seven years, died from heart disease and dropsy. Note the evidence of hereditary tendency. One sister died from "heart disease and dropsy" at the age of twenty-seven years; another sister aged thirty-two years is now suffering from some disease of the heart. Considering that these are young persons, the period of advent of diseases of degeneration not having arrived, there is the highest probability that the heart diseases were and are of a rheumatic kind. The patient takes little alcoholic stimulants. She has had three attacks of rheumatic fever besides the present one, the first attack occurring when five years old, the second when twelve years old, and the third when nineteen years old. The rheumatic proclivity, therefore, is undoubted. Her present illness began about a fortnight before admission, when she had an attack of shivering followed by flushings of heat and by nausea. Pains began in the knees, spreading all over her body, accompanied by headache. After her admission into the hospital, when in bed, she was quiet and comfortable; she slept well, though the left knee was hot and painful, and there was some effusion into the joint. There was no sour smell to be detected. Her tongue was coated, the appetite bad, and the bowels costive; her pulse was soft and compressible. The heart's apex seemed to be in the fifth interspace in the nipple line. The cardiac dulness did not notably deviate from the normal. On auscultation a soft systolic bruit was heard at the apex and was conducted towards the nipple; there was a slight bruit, systolic in time, to be heard at the left of the sternum in the second interspace. The second (pulmonic) sound was only slightly accentuated. Let us pause for a few moments to consider the significance of these signs. In view of the repeated attacks of rheumatism it is in the highest degree probable that there should have been endocarditis; this would most probably affect the mitral valve, and the systolic murmur at the apex showed that some incompetency had been produced. Inasmuch, however, as there were no signs of dilatation of the heart, and as the second pulmonic sound was not markedly loud, the lesion was not considerable. If there had been much regurgitation the backflow would have caused a greater pressure in the pulmonary artery and the second sound caused by the sudden tension of the semilunar valves of the pulmonary artery would have been louder. The

No. 3741.

physical signs in regard to the lungs showed no notable morbid condition. The nervous system was only slightly affected. The patient was intelligent; the speech clear. Except headache and slight vertigo occasionally there was nothing that she complained of, but there was pain on movement of most of the larger joints. Menstruation had been irregular and rather painful. The temperature varied between 103° and 104° F. The urine had a specific gravity of 1015, was acid, of amber colour, and contained no albumen and no sugar. On Sept. 10th great pain about the cardiac region was complained of, and this was increased by deep inspiration. The hands and arms were painful. On Sept. 21st the patient complained of pains all over her body, accompanied by a sore throat. She vomited a good deal of dark, greenish fluid. The temperature, which had been between 97° and 100° for a week, rose for the last two days to between 100° and 102°. The bruit at the apex was still systolic in time, but seemed much longer and harsher. On Oct. 1st the second pulmonary sound was noted to be louder, and there was a presystolic murmur as well as systolic, but no visible pulsation. On Oct. 8th a double second sound was heard at the apex, but not at the base; the presystolic murmur was not so well marked. This double sound had the characters presently to be described; the position and area of audibility are noted on the chart (Fig. 1). On Oct. 15th the second sound at the

FIG. 1.

Positions of the auscultatory signs. Pr S, area of presystolic murmur. The dotted oval above this indicates the area of audibility of the doubled sound in diastole. At M the repeated element had the sound of murmur; at T the sound of tension.

base was well marked, but not loud. Over the pulmonary valves the second sound was heard less acutely than over the aortic area and it was loudest at the ensiform cartilage. On nearing the apex a systolic, blowing murmur was heard and there was a dull sound after the second sound in diastole. The heart sounds were not heard at the back. On Oct. 22nd the double sound in diastole was heard internal to the apex following a blowing, systolic murmur. The patient was discharged on Oct. 29th; there were then no cardiac discomforts or arthritic symptoms.

Let us now consider the progress of the case, which was placed under our usual treatment by salicylate of sodium. The temperature, of remittent type, went down in a very satisfactory way for seven days, and on the eighth was slightly below the normal, that being on Sept. 13th. During this period, however, though the joint symptoms receded, there

was much pain in the heart region increased by deep inspiration. Then, after some slight subfebrile manifestations, the temperature began to rise again, so that on the evening of the 21st it was 102.5° , and this in spite of treatment by the salicylates. The signs in regard to the heart altered; the systolic bruit at the apex at first became more prolonged and harsher, the second sound over the pulmonic valves louder, and on Oct. 1st a presystolic murmur was heard. This soon became less audible, but another phenomenon took its place. Three sounds at, or slightly internal to, the apex were heard. (1) A blowing systolic murmur; (2) the second sound having the characters previously noted; and (3) a dull sound, as of tension, in diastole. This is the phenomenon which has been described as reduplication of the second sound, and occurs in more than half the cases—probably nearly all—of mitral stenosis at some period of their history. Let us endeavour to trace the evolution of the endocardial lesion in this case in the light of the physical signs observed. As I have said, there was probably in this patient before the acute illness began some old rheumatic changes about the mitral orifice which had brought about a slight incompetence of the valve. With this attack there was a new outburst of rheumatic endocarditis, and the first indication of this was the increased prolongation and roughness of the systolic murmur at the apex. Then we became aware of a presystolic murmur, probably because a ring of vegetations obstructed the current of blood from auricle to ventricle. For some reason, however, this presystolic murmur disappeared; it might be that the surface over which the blood had to pass became less rough. But we had at one spot near the apex a triple sound just like that known as a reduplicated second sound, and at another spot still nearer to the apex (yet both within an area which you could cover with a half-crown piece) a triple sound, divisible thus: (1) the systolic murmur, (2) the second sound, and (3) a short murmur in the early portion of diastole. Now if in your observation of a case of rheumatic fever—during or long after the febrile period—you find such a triple sound at or near the apex, you may be almost sure that your patient will ultimately manifest signs of obstructive disease at the mitral orifice—mitral stenosis. Dr. Cheadle, in his Harvelian lectures on the Rheumatic State in Childhood, has confirmed my views as to the significance of this sign, and so have other observers. Dr. Cheadle has limited the significance of the phenomenon as prophetic of mitral stenosis to the cases in which it is audible only at or near the apex—that is to say, in the mitral area. A long series of observations has taught me that, whilst in the early periods of the cardiac disease the triple sound is heard only at the apex, as years go on it becomes more marked at the base of the heart and less at the apex, the presystolic murmur occupying the area of the formerly heard triple sound, the latter becoming more and more pronounced at the base. In the case we have just observed the obstruction at the mitral orifice was evidently brought about by an acute attack of rheumatic endocarditis. Granulations formed about the ring to which the mitral flaps are attached. Probably the borders of the valve near the auriculo-ventricular orifice have become thickened and fused together, and ultimately the mitral curtains will be converted into a membranous funnel. In a large number of cases of mitral stenosis an acute rheumatic origin is not to be traced. The affection arises very gradually without rheumatic symptoms, though a great majority of the subjects thereof show hereditary predisposition to rheumatism. In a minority of cases I think it most probable that the affection arises without any intervention of rheumatism, the form of endocarditis being quite distinct from the rheumatic. On this point we shall obtain some evidence in our consideration of the next case.

CASE 2.—A man aged forty-two years was admitted on Oct. 11th, 1894, for nephritis. His father lived to the age of seventy-five years, and suffered from gout; his mother died at seventy-seven years of age, the cause of death not being known. One brother and three sisters are alive and healthy. There were eight other children, but the patient thinks they all died in childhood. He has lived for many years in London, though born in Devonshire. He says he drinks about one pint of ale a day. There is no history of rheumatism nor of syphilis. He seemed quite well in July, when he had an attack of inflammation of the kidneys, for which he was treated as an in-patient at this hospital and after fourteen days was discharged. He was slightly œdematous and had considerable œdema of the lower extremities; he lay quietly and comfortably in bed, and suffered no pain except

occasional headache. The tongue was dry and slightly coated; the bowels regular. There were some dyspeptic symptoms—viz., distension and pain after food. The liver and spleen seemed normal. The apex of the heart was in the fifth interspace; the cardiac dulness was not more than normal, perhaps less. On auscultation a systolic murmur was heard at the apex. Examination of the respiratory system showed no abnormal signs, except a few rhonchi over both lungs. The patient occasionally suffered from incontinence of urine. Examination of the eyes showed high myopia (about -18) a large amount of choroidal atrophy with a little pigmentation. The specific gravity of the urine was 1016, about one-eighth albumen, and no sugar. On Oct. 18th the albumen had increased to one-half. There was no murmur at the apex, but a double second sound was heard—i.e., after the normal second sound and a considerable pause a dull shock-sound was heard in about mid-diastole. This doubling of the second sound was confined to the neighbourhood of the apex. The area of audibility and the characters of the sounds are indicated on the chart (Fig. 2). The radial artery was cylindrical, its coats

FIG. 2.

Dotted outline shows the area of audibility of the doubled sound in diastole. T, sound of tension; M, of murmur.

moderately thickened; the pulse was slow, 52, tension rather above normal but quite regular. On Oct. 25th the aortic and pulmonic second sounds were well marked, but not loud. The pulmonic was not quite so loud as the aortic. The double sound was still heard in the interspace below the nipple, but not so well-marked. The doubling was rendered more decided by the patient sitting up and extending his arms above his head. On Oct. 27th the patient felt quite strong; his appetite had much improved. The pulse was 54. There was still one-third of albumen in the urine. On Nov. 8th the patient felt much better. The pulse was 60. A double second sound was still heard at the apex, inaudible except within the area marked upon the chart.

You will notice how closely the auscultatory phenomena in this case resemble those in the former with the exception that there never had been as yet a presystolic murmur. The murmur was in mid diastole. This patient had manifested no trace of rheumatism; there was no tendency to rheumatism in members of his family. The phenomena seem to be in sequence to renal disease. Will this patient also manifest the condition of mitral stenosis? Very probably, for we have evidence that gout and renal disease are associated in a

very marked degree with mitral stenosis in persons of later adult life. It seems probable that the obstruction at the mitral orifice may be due to fibroid and degenerative changes involving the curtains of the valve, the chordæ tendineæ, and the muscular columns without the occurrence of an initial endocarditis. Let us now consider more minutely the phenomena we have observed and endeavour to obtain an explanation of them. First, as to the *mode of observation*. In the process of auscultation in the usual way you become aware as you get nearer to the apex that three sounds are audible. I placed my stethoscope at a point internal to that of the apex beat, and I asked my clinical clerk how many sounds he heard. His answer was "Three." Now, you know well that in the majority of cases, whether in health or in disease, you hear two sounds, the dull and more prolonged first sound followed by the shorter, sharper, or less dull second sound. In some cases you hear only one sound and that the first; the second sound is inaudible at the apex. In the cases under observation we marked with a dermatographic pencil the area over which we heard the three sounds, or the triple sound if you like so to term it. Having done that we listened again over the area in order to distinguish the characters of the sounds. We found no difficulty in determining which was the first sound—i.e., that which was coincident with the apex beat. We then observed that over a spot near the apex the second element of the doubled sound which followed this had the character of a brief roughness or blow, whilst a little nearer to the sternum it was a sudden but dull sound giving the idea of tension. We marked these positions on the chest wall: M for murmur, T for tension. Then we passed over the marked areas a pencil dipped in oil, outlining also the positions of the adjoining intercostal spaces and the ensiform cartilage. Over the surface we pressed a sheet of copying paper and obtained a print of the relative positions of the signs we had observed. I gave these outlines to Mr. Daniellson, who has reduced them to a convenient size and cut the woodblocks, Figs. 1 and 2, which indicate as exactly as can be the areas of audibility of the sounds. I must ask you to note that at some periods the murmur sound was inaudible, the tension sound being evident after its first appearance for all the periods during which the patients were in the hospital. We have had evidence, however, that the doubled sound may in some cases altogether disappear for a time. Now I must ask you to pass from the consideration of these two cases to that of a large number of others of mitral stenosis which I have observed, and let me tell you what I deem to be the changes in the auscultatory phenomena as the months and years go on. The isolated murmur sound disappears and a typical presystolic murmur takes its place; the repeated sound of tension becomes more pronounced and its area of audibility changes; it mounts to the fourth, third, and second left intercostal spaces, and in some cases we hear it on the right of the sternum as well as at the left. It becomes a sharper, louder sound, closely resembling an accentuated second sound. It vividly recalls the postman's knock. In one case I have heard this in a most marked manner at the back just internal to the angle of the left scapula. Still later the doubled sound wholly disappears, and when a case of mitral stenosis nearly approaches heart failure the presystolic murmur itself may no longer be heard. To return to our method of recording the signs observed we will attempt to indicate the positions these occupy in the cardiac cycle. We draw a straight horizontal line, which is supposed to represent the duration of one cardiac revolution. We intersect it by a vertical line, which indicates the commencement of ventricular systole, and divide it into two unequal portions by another short vertical line, which designates the commencement of ventricular diastole. Say, for argument, that the pulse is 60 and that the period of systole occupies four-tenths of the whole length, and that of diastole (the long pause) six-tenths. The distance between the first and second vertical lines, indicating the commencement of ventricular systole and of ventricular diastole respectively, will comprise four time divisions, and that between the second vertical line and the commencement of the succeeding systole—i.e., the long pause—six divisions. Of course the indications are approximate only, but they are convenient aids to precision. In our first case we listen at the base of the heart, and fix in our minds the time position of the second sound, and then on nearing the apex we find that the next tension sound takes place very quickly after it; the doubled sound is heard in the early part of diastole. In the second case there is a

considerably longer interval between these sounds. In fact, the doubled sound of tension seems to be nearly in the middle of diastole, and the sound of murmur heard a little nearer the apex appears in a similar position (Fig. 3).

We will now consider the question of the cause of the double sound of tension that we hear in cases of mitral stenosis. There are two theories as to its mode of production. According to the first theory, which has been generally accepted, there is a real doubling of the second sound of the heart—the valves of the aorta and of the pulmonary artery do not close as in normal conditions, giving rise to one sound, but those of the one vessel close before those of the other, the interval of time being sufficient for the ear to appreciate two sounds. So the second sound of the heart is said to be reduplicated. According to the other theory the doubling of the second sound is not real but simulated. The second sound is heard in the normal way, but it is followed by another shock-sound (or sound of tension), which is produced not at the valves of the great arteries but in the left ventricle.

FIG. 3.

Showing the estimated positions of the sounds in the second case. S, systolic murmur; 2, second sound; T, interpolated sound of tension; M, interpolated sound of murmur.

It is this last view of the mechanism of the phenomenon which to me seems correct. Before proceeding further let us ask ourselves what is the cause of the normal second sound of the heart. The answer usually given to this question is this: the semilunar valves of the aorta and pulmonary artery respectively, after the forcible injection of blood into the aorta by the ventricular systole, come together suddenly, and the sound is produced by their concussion. Look at the delicate membrane of these valves. Is it probable, do you think, that the edges of these structures should strike together with sufficient force to produce the snap of the second sound more than 90,000 times a day through the years of a long life without injury from the mere violence done to them? Now the most careful and most recent investigations show that in the systole of the ventricles there is not an abrupt and sudden injection of blood into the great vessels (the aorta and pulmonary artery), but, though all occurs in a brief period of time, a graduated series of successive movements and coördinated actions. First, the muscles of the ventricular wall commence their contraction; shortly afterwards, but yet appreciably later, the muscoli papillares begin and continue to tug down the curtains of the valves by their tendinous cords; then these relax while yet the muscles of the wall are contracted; lastly, the ventricular muscle relaxes also and then active dilatation (suction) in diastole begins. It is a natural consequence that the impulsion of the blood into the great vessels is not abrupt, but gradual, and the closure of the semilunar valves must be not abrupt, but gradual. At first the force must be insufficient to overcome the inertia of the blood in the vessels weighing down the cusps; then by the combined forces of the contractions of the ventricles and the papillary muscles these semilunes are gradually opened out; but towards the end of systole the force of impulsion is diminished—there is more pressure above the valves on account of the increased volume and distension there, but decreased pressure below as the ventricle becomes emptied and the papillary muscles no longer reinforce the muscular walls of the ventricle. This reasoning shows us (as Mr. Mayo Collier pointed out in his Lectures on the Physiology of the Vascular System at the Royal College of Surgeons of England in 1889) that the semilunar valves do not come together suddenly and abruptly, but gradually. The volume and tension of the blood above them tend more and more to weigh them down, while less and

less blood passes through them from the ventricle. What, then, is the cause of the second sound? The answer is: the sudden tension of the membranes of the already closed valves caused by the relaxation of the ventricles, whereby they are no longer supported on their under surface, and the active suction action of the ventricles in the earliest part of the diastolic period. You can imitate this sound of tension by abruptly stretching an inch of your pocket-handkerchief between your fingers. Now supposing this explanation of the phenomena to be correct, as I believe it is, if we accepted the view that the reduplicated second sound is due to non-synchronous tension of the two sets of valves we should have to concede that the two ventricles expanded in diastole at different times—that there was a sort of see-saw action between them—of which we have no evidence, but much to the contrary.

But let us turn to a practical question. How shall we investigate the second sound of the heart? Place the end of your stethoscope over the second right intercostal space close to the sternum and listen attentively to catch the character and pronunciation of the second sound. Then carry your stethoscope up nearer to the right clavicle, to the episternal notch and over each carotid. Note the degree of audibility and the character of the sound in all these situations. You can have no doubt that the sound you hear in these areas is that produced by the tension of the aortic semilunar valves. Now carry your stethoscope to the left of the sternum; listen to the sound over the second and third left intercostal spaces, comparing it with that you have already heard. If you find the second sound to be louder in these situations than in the former you may conclude that it is the tension of the semilunar valves of the pulmonary artery which is the chief cause. The pulmonic second sound is accentuated. Recent observations have tended to show that the sound of tension of the pulmonary semilunar valves is heard over a very limited area. Dr. Sydney Ringer and Dr. Phear, in an interesting and valuable communication,¹ conclude that the pulmonary element usually forms no part of the second sound as heard to the right of the sternum. "The second sound heard to the right of the sternum is produced, as a rule, exclusively by vibrations generated at the aortic orifice." Dr. William Ewart² has further insisted that the pulmonary second sound has a singularly limited area of loudness. He gives elaborate anatomical and other reasons for concluding that the audible vibrations in the case of this sound are conducted only to the anterior chest wall immediately covering the valve as well as to a limited adjacent district. When you place your stethoscope to the left of the sternum below the level of the third interspace you get out of the range of the pulmonic second sound. You should observe the characters of the sound, however, as far as the heart's apex and note where it becomes inaudible. Sir William Broadbent³ stated that the second sound as heard at the apex is that due to the aortic valve alone. The aortic second sound is conducted by the wall of the left ventricle and is often heard as distinctly at the apex as in the aortic area itself. Dr. Ewart has enforced this teaching; he concludes that the right side of the heart does not conduct the pulmonic second sound. "The aortic second sound commands these cavities (the pulmonary artery through its right branch influencing only the left auricle) in addition to holding the high road for vibrations along the septum, and so practically excluding the pulmonary sound from propagation into the right ventricle." You will, therefore, form your conclusion as to the characters of the aortic second sound from auscultating not only over the second right interspace, the episternal notch, and the carotids, but also over the interspaces below the third interspace on the left side and as far as (and even beyond) the apex of the heart, whilst the characters of the pulmonic second sound will only be found when you listen over the second and third left intercostal spaces near the sternum.

Now as to the relative pronunciations and characters of these two components of the heart's second sound respectively. With regard to the aortic second sound there are two conditions in which we find it especially loud. It may have a sudden, sharp character, or be almost metallic, or like a tap upon a small drum. The two conditions to be especially mentioned are: (a) sacular aneurysm of the thoracic aorta arising well above the valves, and

(b) hypertrophy of the left ventricle, especially with arteriosclerosis (as in chronic renal disease). In the first of these conditions the loud sound is readily explained by the exaggerated strain upon the valves directly on ventricular relaxation (diastole) caused by the abnormal mass of blood pressing downwards from the aorta and its saccular dilatation. In the second, after the forcible injection there is a forcible recoil, the firm-walled contracted arteries increasing the back pressure. Dr. Ringer and Dr. Phear have given experimental evidence emphasising the conclusion that high arterial tension is a cause of a loud aortic second sound. I agree, however, with Dr. Ringer and Dr. Phear, and with Dr. Harry Campbell,⁴ when they say that the aortic second sound may be accentuated when the radial (arterial) tension is low. I think with Dr. Campbell that this accentuation is due to an abnormally sudden and rapid diastole of the left ventricle. With regard to abnormal loudness of the pulmonic second sound the cause is over-tension of the blood in the pulmonary artery and its branches. This occurs in its most pronounced degree in mitral regurgitation—and is then, if the ventricular forces are adequate, proportionate to the amount of blood thrown back by the left ventricle into the left auricle and pulmonary veins—and in mitral stenosis when a direct impediment occurs to the work of the right ventricle because the left auricle cannot, as under normal conditions, sufficiently transmit its contents through the obstructed orifice into the left ventricle. There are, however, many other causes for undue loudness—in its limited area—of the pulmonic second sound. We find a loud second sound over the pulmonary artery in chlorosis and anæmia, in states of general feebleness especially after acute and debilitating illnesses, in many diseases of the lungs, and in cases of retraction of the lung and uncovering of the heart, so that the pulmonary artery comes closely in apposition to the wall of the chest. Any cause which weakens the left ventricle and so diminishes the amount of blood which it should transmit to the aorta tends to accumulation of blood in the pulmonary artery and its branches and to an abnormal tension within the vessel evidenced by an exaggerated second sound heard just over its valves. In many of the conditions we have just discussed there must be very disproportionate pressures in the two great vessels, the aorta and the pulmonary artery. We get accentuation of the second sound in one or other area, or in both areas; but very rarely we observe doubling—so-called reduplication. In very free mitral regurgitation the disproportion must be extreme. We observe constantly, unless the right ventricle is too weak, the loud pulmonic second sound, but a doubled second sound, I think I may say, never. In mitral stenosis, on the other hand, when the disproportion of pressure is probably less marked, the so-called reduplicated second sound is very common indeed. Now, if the phenomenon of the repeated sounds were really due to the sound of tension of the semilunar valves of the one vessel being followed at an interval by the sound of tension of those of the other, you ought to be able to hear the double sound best to the aortic side of the second left interspace or, at any rate, at a point not lower than the third interspace, where the pulmonary second sound becomes inaudible; but in our cases, and in many others, the double sound is not heard except in an area in which most of us agree that the pulmonic second sound is inaudible. You will notice that in our two cases the doubled sound is heard only in the neighbourhood of the apex. Do not misunderstand the point for which we are contending. Observers are, I think, for the most part agreed that what they call "reduplication of the second sound" is very common in mitral stenosis. I have shown that in the early stages of the development of mitral stenosis this so-called reduplication of the second sound is audible, not at the base, but near the apex of the heart. This has been confirmed by many observers. Dr. Ringer and Dr. Phear, in their criticism of my opinion,⁵ object that such reduplication at the apex is very uncommon. We have had, however, many opportunities lately, and at previous periods, of observing the phenomenon, and, as I have said, many clinical observers have noted it also. If the instances were still more rare, from the admitted data as to the range of audibility of the two components of the second sound, it must be agreed that non-synchronous tension of the valves of the pulmonary artery and the aortic respectively could not explain them. The second element of the sound is in the

⁵ Loc. cit., p. 730.

mitral area, and I have given many reasons for the conclusion that it is produced within the left ventricle.⁶ No doubt the so-called reduplication is more frequently observed near the base of the heart than at the apex in cases of mitral stenosis because these are less frequently met with at the earlier periods of their history. It would be strange, however, if we should have to invoke a totally different cause for the production of the phenomenon in the same case at different periods. When in a case of mitral stenosis the doubled sound is heard at the base of the heart its maximum is, as Sir William Broadbent pointed out, over the third left intercostal space close to the sternum. It may be heard, however, over a very wide area to the right and down the sternum far beyond the area given as the limitation of audibility of the pulmonary second sound. I have heard the double sound loudly, having its typical characters, in the left axilla and at the angle of the left scapula.⁷ The pulmonary second sound could take no part in this. The explanation that I have given of the so-called reduplication of the second sound in cases of mitral stenosis is this: the first element is the normal second sound, probably accentuated as to its pulmonary component; the second element is a sound of shock or tension within the left ventricle produced by a sudden entry of blood into the ventricle in early diastole, such shock being communicated to the walls of the ventricle or to the anterior curtain of the diseased mitral valve, and so communicated through the septum to the left border of the sternum. Dr. Ringer and Dr. Phear say that they "are unable to understand how, even after the relaxation of the ventricle, the blood can enter through the contracted mitral orifice with any degree of force, or how the diseased and thickened valves can be thrown into such a condition of tension as to produce a valvular sound simulating the second sound." The answer to this is that the constriction at the mitral aperture is a matter of degree; the funnel orifice in many cases could surely permit in diastole a sudden entry of blood into the ventricle with considerable force. On this point the evidence of the cardiograph comes to enlighten us. In some cases of undoubted mitral stenosis there are signs which I think all would agree to be explicable by no other hypothesis than that the entry of blood into the ventricle is forcible and sudden than under conditions of health. Remember that the pen of the cardiograph is guided by the left ventricle. The record of the diastolic period is written by the apex of the ventricle because of impulses or movements which it receives from the auricle. The consensus of many observations shows that in mitral stenosis (evidenced by a rolling or bubbling presystolic murmur) the apex of the ventricle writes a series of up-and-down lines and curves which can only be due to the impulses of the interrupted, gurgling flow from the auricle. In a case of typical doubling (as it were of the second sound) I have seen the eminence due to the contraction of the auricle more broad and pronounced than I have observed it under any other circumstances whatever. It must be that the mitral orifice, though narrower than the normal, allows the forcible contraction of a hypertrophied and dilated auricle to communicate a strong upheaval to the apex of the left ventricle. I cannot doubt that under the circumstances of over-tension in systole in the left auricle, as in mitral stenosis, there can be sudden and forcible entry of blood into the ventricle in the early part of diastole sufficient to communicate a shock to the structures within the cavity and (from the considerations I have already placed before you) to give rise to an audible sound of tension. I quite concede that there are other cases of extreme stenosis (button-hole mitral, for example, with greatly thickened borders) where it would be illogical to conclude that the passage of blood from auricle to ventricle could be sudden and forcible; but these are, so far as I have observed, precisely the cases in which the so-called reduplication of the second sound is not heard.

I have, I think, given sufficient reasons for the conclusion that the double sound simulating a repetition of the second sound in mitral stenosis is not due to non-synchronous closure of the valves of the pulmonary artery and the aorta respectively. I believe that the second element of the double sound has its origin in the left ventricle, but I do not pretend that the precise explanation of the phenomenon is placed

beyond all doubt. Be it remembered that I have contended all along for an explanation of the phenomenon as observed in cases of mitral stenosis. In these I have said that the doubling of the second sound is simulated, not real. I will not go so far as to deny the possibility that under conditions other than those of mitral stenosis the second sound of the heart at the base may be heard as a double sound.

TWO CASES OF ULCER OF THE DUODENUM IN WHICH LAPAROTOMY WAS PERFORMED, WITH REMARKS ON ULCERS OF THE DUODENUM.¹

BY A. MARMADUKE SHEILD, M.B. CAMB., F.R.C.S. ENG.,
ASSISTANT SURGEON AND LECTURER ON PRACTICAL SURGERY,
ST. GEORGE'S HOSPITAL.

WRITERS on general medicine who refer to ulcer of the duodenum treat of the subject in general terms. The affection is classed with gastric ulcer, which in all respects it closely simulates, and little or no attempt is made to distinguish between the pathology or symptoms of these two kinds of cases. There is a general opinion that gastric ulcer is rare in men, and, therefore, when duodenal perforation occurs in the male sex the symptoms are peculiarly liable to be overlooked or entirely misunderstood, since they are identical with those of perforation of the stomach, which is so exceptional in the male sex. What is held by physicians of the present day regarding duodenal ulcer may be well summed up by quoting from the article on it in the "American Text-book of Medicine," edited by Pepper:² "Duodenal ulcer is usually single, but is occasionally multiple. In some cases it occupies partly the duodenum and partly the pylorus. In other instances distinct ulcers may be found in the stomach and duodenum. The disease may attend septicæmia, probably as the result of embolism. Severe burns are also at times productive of it, and freezing is said to act in the same way; while erysipelas, pemphigus, and amyloid degeneration of the bloodvessels of the intestines have also been claimed to be associated with it. The symptoms are in a great majority of cases identical with those of gastric ulcer, and it is then impossible to distinguish between the two lesions. An ulcer of the duodenum is probably present if the pain does not develop until some hours after eating food; if the position of this pain, together with tenderness on pressure, is situated decidedly to the right of the middle line; and if there are profuse bloody stools without vomiting or hæmatemesis. In other cases blood may be vomited and passed by stool. In still others the course of the disease may be entirely latent." It will serve to make more clear the class of cases I especially wish to illustrate if I quote a typical instance, selected from several which are scattered about in medical literature. The case I will first draw attention to is related by the late Surgeon-Major Robinscn of the Scots Guards.³ A healthy and muscular guardsman aged thirty-eight years, who was a "bandsman" and well able to perform his duties, played a game of racquets one afternoon and afterwards proceeded to a music-hall where he ordinarily performed. He was suddenly seized with violent abdominal pain. The abdomen became tympanitic, but there was no urgent vomiting. He was conveyed back to bed, collapse supervened, and he died in about eighteen hours. At the necropsy the whole of the intestines were matted together and there was some greenish fluid in the abdomen. The bubbling of gas drew the attention of the pathologist to the duodenum, and an ulcer large enough to admit a crowquill was found about the centre of that viscus on its anterior aspect. This was not in the least suspected during life, but it is stated that the man had been known to complain of epigastric pain and to press his hand there after laughing loudly. The above abstract well exemplifies what usually happens in these most distressing and mysterious maladies, and the theory of death by poison may readily be started when the surroundings and concomitant circumstances are of a suspicious nature. Murchison relates

such a case where a man died almost instantly from collapse; and a similar case is referred to by Perry and Shaw in their excellent article on Ulcers of the Duodenum in Guy's Hospital Reports for 1894.

I was induced to bring the following two cases, which occurred in my own practice, before the Medical Society of London because they so well illustrate the extreme difficulty that is met with in the diagnosis of duodenal ulcer, and because it is only by a relation of cases, and a collection and consideration of the experiences afforded by them, that we can hope to arrive at anything like proficiency in the management of a class of maladies so protean in their clinical manifestations and so generally unsatisfactory in their treatment. Moreover, the subject has been already dealt with, and it is hoped that this communication may extend and amplify information already acquired. The first case which forcibly drew my attention to the surgical difficulties and uncertainties which surround the subject of duodenal ulcer was as follows. (I am indebted to Mr. Harold, the medical registrar of Charing-cross Hospital, for the abstract notes of it.)

CASE 1.—A healthy-looking young man aged twenty years was admitted under the care of Dr. Green on Nov. 30th, 1892. His previous history was of little importance. There was a vague account of some epigastric pains and flatulence, but while sitting at the theatre he was seized with severe pains in the abdomen "which doubled him up," and he was brought to the hospital on the above date. It was then noted that he was in a condition of collapse. The skin was pale and covered with clammy sweat, the temperature 96° F., and the pulse 100, small and compressible. Severe abdominal pain was complained of, and the abdomen was distended. There was marked tenderness in the epigastric region. There was no vomiting as yet, and flatus was passed per anum. He was treated with morphia and bismuth. Towards the evening his symptoms got worse. The abdominal pain and distension were greater, and he vomited several times greenish, and subsequently stercoraceous, fluid, but no blood was noticed in the vomited matter. On Dec. 1st, after a hypodermic injection, the patient had slept fairly well, but he had vomited several times, and the abdomen was very much distended. I saw him on Dec. 2nd, the third day of his attack. He then had the appearance, and showed the usual symptoms, of one suffering from a serious abdominal malady, and his condition was obviously very precarious. The abdomen was enormously distended, and the main seat of tenderness seemed to me to be below, near the cæcal region. The diagnosis of perforative peritonitis was made, and the opinion expressed that the lesion was situated in the vermiform appendix. Not having seen the case from the commencement my mind was hardly enough impressed with the situation of the pain in the epigastric region in the early part of the case, and hence an error was made in the estimate of the position of the perforation. The abdomen was explored by the usual incision. To my disappointment the cæcum and appendix were found to be normal. The intestines were congested, covered with lymph, enormously distended, and the abdominal cavity full of purulent fluid and some gas without fecal odour. The incision was made nearly up to the ensiform cartilage, but nothing was made out, for the intestinal distension made examination very difficult, and the desperate condition of the patient forbade delay. The abdominal cavity was therefore washed out and closed. The patient, as is usual in such cases, died about twenty-four hours later, pulseless and collapsed. One could hardly say that the operation did him harm—it certainly failed in doing him any material good. At the post-mortem examination a perforating ulcer was found on the anterior aspect of the first part of the duodenum. The opening was circular in form, about the size of a threepenny-piece, and had thickened, callous edges. This was obviously the cause of the general peritonitis. All the other organs and viscera were healthy.

CASE 2.—This occurred in the person of a strong young man aged twenty-three years who was under the care of Dr. Whipple at St. George's Hospital on June 11th. He had been quite well until five days before admission, when he was seized with violent abdominal pains, vaguely referred to the right side. He had vomited several times, but the bowels had opened twice. Three years ago he had a similar attack and had got well. The significance of this latter statement will be seen further on. I saw him, with Dr. Whipple, soon after midnight. He looked fairly comfortable, but the pulse was very quick and the abdomen greatly distended. The hernial apertures were empty and the rectum was devoid of feculent contents, but a sensation of fluid in the pelvis

could be felt through it. No very marked tenderness could anywhere be elicited. When the patient was asked where his worst pain was situated he pointed to the right iliac region. Here also there was tenderness on pressure. Previously on the same night I had operated upon a case of a very similar nature and had found a perforation of the vermiform appendix, and I could not divest my mind of the belief that the present case was due to a similar cause, and thus again fell into error. I may, however, mention that the possibility of duodenal ulcer was actually present to our minds, and we discussed it. The abdomen was opened in the right linea semilunaris, and immediately enormously distended coils of bowel showed themselves, deeply congested and covered with lymph. There was purulent fluid in the pelvis and bubbling of gas, but this was quite devoid of fecal odour; its reaction to litmus paper was not ascertained. The cæcum and vermiform appendix were with some trouble examined and were found to be normal. So great was the intestinal distension that I opened a prominent coil of jejunum by a small incision and drained away many basinsful of feculent fluid. The incision was closed with a Lembert suture and the collapsed bowel permitted free exploration of the intestine. Nothing could be found, and in reflecting upon the time that would be consumed by prolonging the incision with the view of finding an ulcer of the stomach or duodenum and repairing it I reluctantly closed the abdomen and left in a glass drainage-tube, having well flushed out the abdominal cavity with warm water. This patient seemed at first much relieved, but on the evening of the day following the operation he had a recurrence of severe abdominal pain and soon died. At the post-mortem examination it was revealed that there was a small ulcer which would admit a quill on the anterior wall of the duodenum, about half an inch from the pylorus. The hole was rounded, with thick discoloured edges. At the same level with the ulcer which had perforated there was a depression about one-third of an inch in diameter, smooth, and the walls not undermined. This was evidently an ulcer which had healed. It was situated on the posterior wall of the duodenum. There was general peritonitis, and a large cavity containing about two pints of brownish fluid was situated above the stomach and below the liver and diaphragm. The abdominal wound had united, and it is especially important to observe that the small incision made to drain the intestine had soundly healed in less than twenty-four hours, demonstrating the safety of the procedure of draining distended intestine.

Before proceeding to the discussion of the general question of duodenal ulcer I will shortly quote abstracts of two cases strikingly similar to those first related, which demonstrate the fact that I do not stand alone in the diagnostic difficulties which surround perforating ulcer of the duodenum. Perry and Shaw in their recent article state that laparotomy was thrice performed at Guy's Hospital for perforative ulcer of the duodenum, but the lesion was never found. Lockwood⁴ relates the following cases of great interest in the Medical Society's Transactions. The first case was that of a young man aged twenty-eight years who was suddenly seized with acute pain on the left side while drinking a cup of tea. This was thought to be an attack of colic, and treated accordingly. Vomiting and tympanites with complete obstruction supervened, but there was no hæmatæmia. On the third day an exploratory abdominal section was performed, and a quantity of foul-smelling gas escaped, while general purulent peritonitis was present. The whole intestine was examined, but no perforation was found. The distended gut was opened and drained, and the opening closed by a Lembert suture. The abdomen was flushed out. The patient died in seven hours. The chief focus of septic peritonitis was found below the liver, and upon the front part of the duodenum was a small oblong aperture, which gave exit to the duodenal contents. The second case was that of a man aged forty-one years who while at his work was suddenly seized with violent pain in the abdomen followed by complete constipation and sickness. The vomited matter was at first the contents of the stomach, and afterwards of a stercoraceous nature. When first seen the abdomen was tympanitic and no vermicular movements were detected. The countenance was anxious and the man complained of severe abdominal pain. The pulse was 120 and the temperature 99° F. The abdomen was explored through the usual incision. Diffuse

⁴ Post-mortem and Case Book, St. George's Hospital, 1894.

⁵ Transactions of the Medical Society of London, vol. xv., p. 91.

septic peritonitis was found, but although every region was searched nothing could be found to account for its occurrence. The man died in ten hours, and Dr. Galloway, who made the post-mortem examination, found the most intense focus of inflammation beneath the liver. The first part of the duodenum was perforated by an ulcer, which had sloping edges, situated about an inch from the pylorus.

The abstracts of these two cases clearly show that the diagnostic difficulty felt by myself and illustrated in the instances I have narrated is shared by other surgeons; and now that it is recognised that the prompt treatment of perforating gastric ulcers by abdominal section saves life the present time seems peculiarly opportune for drawing the attention of the profession to perforating ulcers of the duodenum, which so closely resemble them. It has seemed to me that the compilation of statistical tables as to the comparative frequency of duodenal ulcer or of certain of its more marked clinical features would be open to many sources of inaccuracy and would serve little useful purpose. The undoubted fact that the scars of duodenal ulcers are sometimes accidentally met with post mortem shows that this condition may not infrequently be recovered from when perforation does not occur, and is a proof that many cases are accidentally overlooked. Perforating ulcer of the duodenum is no doubt a rare affection, and a proof of this statement is found in the observations of Norman Moore,⁶ who finds that only three cases are recorded in the St. Bartholomew's Hospital post-mortem books between 1867 and 1882, a period of sixteen years. Two of these occurred in men, and showed the usual features of sudden and unsuspected onset. In one of them the ulcer was not even suspected during life. It seems clear from the elaborate researches of Dr. Perry and Dr. Shaw, as well as from the perusal of these cases, that the ulcer is almost invariably found on the anterior surface of the first part of the duodenum. Out of 57 cases of rapidly perforating ulcer collected by them the lesion was situated here in 48. I am greatly indebted to valuable assistance from Mr. Arthur Latham in looking up the question of the frequency of duodenal ulcers in the post-mortem books of St. George's Hospital. He finds that in 8192 post-mortem examinations in the thirty-one years from 1863-1893 there were 116 cases of death from perforation of the intestine (from all causes save rupture); that is, 1·4 per cent. of total deaths. These 116 include 12 cases of perforating duodenal ulcer—that is, 0·14 per cent. of total deaths and 10·34 per cent. of all perforations.

Cases of Perforating Duodenal Ucer.

—	Year.	No.	Sex.	Age.
1	1892	157	Male	34
2	1891	306	Female	27
3	1890	404	Male	21
4	1889	206	Male	37
5	1887	165	Male	42
6	1883	225	Male	49
7	1882	235	Female	22
8	1878	190	Male	59
9	1875	172	Male	50
10	1875	175	Male	52
11	1871	34	Male	56
12	1871	42	Male	56

Out of these 12 cases ten occurred in males and only 2 in females. The average age is forty-two years. Out of the 116 cases of intestinal perforation, of non-perforating ulcers of the duodenum, or congestions threatening to perforate, there were found 23 instances which may be thus arranged: burn with slight ulceration or congestion and early erosion, 7 cases; associated with renal disease, 6 cases; phthisis and tuberculosis, 2 cases; malignant ulceration, 1 case; associated with scirrhus of pancreas and liver, 2 cases; and associated with pleurisy, 1 case. The remaining four cases had no obvious causes. In 9 of the 12 perforating cases the ulcer was situated anteriorly; in 3 the situation was not mentioned. I propose (1) to briefly consider the views taken by pathologists as to the formation of these ulcers and to illustrate their pathological terminations; (2) to pass in review their various clinical symptoms, illustrating my

remarks when possible by abstracts of cases; (3) to discuss the appropriate treatment; and (4) to draw conclusions which may seem warranted by the present state of our knowledge.

It is well known that the formation of ulcers in the stomach and duodenum has long engaged the attention of eminent pathologists. Rokitsansky⁷ regards tuberculous ulceration of the duodenum as very rare. He refers his readers for the pathology of perforating duodenal ulcer to his account of a like process occurring in the stomach.⁸ He states his belief that these ulcers commence as an acute, circumscribed, red softening, or with a circumscribed sloughing of the mucous membrane. He speaks of the now well-known usual terminations by cicatrization, perforation, hæmorrhage, permanent contraction, matting, and condensation of tissues round. It will clear the way at the outset to exclude all causes of ulceration of the duodenum from without, as by gall-stones, the pressure of malignant growths, the slow erosion of an aneurysm, or a renal abscess or suppurative connexion with spinal caries.⁹ Instances of all these conditions will be found scattered through pathological literature, but are hardly germane to the subject under consideration. Ziegler,¹⁰ while looking upon the duodenal ulcer as essentially similar in its pathology to ulcer of the stomach, well points out that the latter ulcers, and therefore the duodenal ulcers also, may be caused by any kind of local injury of the mucous membrane which exposes it to the unchecked action of the gastric juice, not yet neutralised in the first part of the duodenum, where these ulcers usually commence. Probably the commonest causes of obstructed blood-supply, leading to necrosis of the mucous membrane, are venous engorgements, hæmorrhages, arterial anæmia from embolism, spasmodic contraction, or arterial sclerosis. What share such morbid conditions as cardiac and renal changes, alcoholism, syphilis, and Bright's disease may have in bringing about these conditions would be too wide an inquiry for the scope of this paper. A word, however, must be said as to the undoubted occasional association of ulceration of the duodenum with albuminuria and renal degeneration, as so ably pointed out by Dr. Dickinson. In the post-mortem and case book of St. George's Hospital for 1890 will be found four such cases where ulcers were found in the duodenum, and in one instance in the cæcum also, in association with the large white kidney and interstitial nephritis. The symptoms during life were vague, and the sickness and diarrhoea might well be attributed to other causes. Perry and Shaw found no less than twelve cases of ulcer of duodenum out of seventy associated with Bright's disease. There seems no distinct proof that albuminuria is associated with the rapidly fatal perforating ulcer which we are principally considering, though of course it may be a predisposing cause.

The association of ulcer of the duodenum with burns and scalds has long occupied the attention of pathologists. It is very remarkable that modern investigators have cast doubts upon this association, and there can be no question that this phenomenon is much rarer now than was formerly the case. Curling's well-known paper in the Transactions of the Royal Medical and Chirurgical Society¹¹ relates ten cases of this lesion associated with burn, while Hewitt, still earlier¹² found three instances of ulceration of the duodenum in seventeen fatal cases of burn examined at St. George's Hospital between the years 1844 and 1846. So Holmes,¹³ writing in his System of Surgery, relates sixteen lesions of the duodenum in 125 cases of burn. The age of the patient and the period of death varied extremely. The appearance, says the latter writer, is that of a perfectly indolent ulcer. It is usually situated just below the pylorus; often there are two or three close together. . . . They look as though a portion of the mucous membrane had been cut out. This writer also refers to the frequent absence or vagueness of symptoms, and where severe manifestations, as mælena, hæmatemesis, and signs of perforation, occur he seems to think the prognosis highly unfavourable. Curiously enough, from an early period doubts commenced to be thrown upon the association of duodenal ulcer in association with burns.

Thus WILKS,¹⁴ writing soon after Curling, made a careful examination of twelve fatal cases of burn and found no lesion in the duodenum. He contrasts his experiences with those of Curling, but gives no explanation of the discrepancy. McCarthy,¹⁵ relating a fatal case of duodenal ulcer from vomiting and hæmatemesis in a girl aged seven years, states that this complication is rare at the London Hospital, only one case besides the one he mentions having occurred for eight years. Lockwood has recently been investigating this subject, and I have his authority for stating that out of 138 fatal cases of burn occurring in the last nine years at St. Bartholomew's Hospital only one had ulcer of the duodenum, although the pathologist had obviously been on the alert to detect duodenal lesions. Perry and Shaw, in the Guy's Hospital Reports for 1894, found 5 cases of duodenal ulcer in 149 cases of burn. In reviewing all the cases of burn ulcer, they find it more frequent in females than in males; this they ingeniously attribute to the burnt surfaces being usually, from the arrangement of the clothes, more extensive. Quite recently also some of the more advanced of the younger school of pathologists have stated disbelief in the relationship between burns and duodenal ulcers. The conclusion is irresistible that some surgeons, especially in former times, had experience of a condition which now seldom exists. The explanation is probably in the direction of sepsis, and the improved methods of cleanliness at present in vogue regarding the treatment of burns. The profuse diarrhoea which accompanies extensive and dirty burns is very suggestive in this respect, and so are the patches of hemorrhagic congestion and inflammation so often found in these conditions through the small intestine. It is easy to understand that if one of these patches occurred in the first part of the duodenum the unrestrained action of the powerful gastric juice not yet neutralised by the bile might readily cause rapid ulceration and perforation. It is striking that ulceration of the duodenum should also have been found in cases of frostbite.¹⁶ Thus Samuel Adams, an assistant surgeon in the United States Army, relates the case of a private aged thirty-six years, who was confined in the guardhouse awaiting his trial by court-martial when both his feet became frostbitten, and when first seen gangrene had already set in. After being in the hospital for a week diarrhoea ensued, with rapid exhaustion. The line of demarcation formed, but the patient died exhausted in about three weeks. At the necropsy the duodenum was found covered with small irregular ulcers with rough serrated edges extending in different directions. It will be observed in connexion with this case that the conditions found in bad burns of sloughing and septic tissues were present, and the explanation is probably the same—namely, an infarction of the vessels of the mucous membrane due to septic emboli, and the consequent unrestrained action of the gastric juice. Post-mortem examinations upon cases of septic ulceration after frostbite have not been very frequent, or possibly duodenal ulcer may have more commonly been found. That ulcers of the duodenum in such septic conditions as burns are due to septic embolism of some small vessels in the intestinal walls seems a more rational explanation than the old theory of hyperexcitation and inflammation of Brunner's glands. Looking upon such embolic processes as almost accidental, it is easy to understand how several cases may occur in the experience of one surgeon and none in the experience of others, and hence very erroneous estimates may be adduced as to the comparative frequency of duodenal ulcer after burns. There is one point which it seems to me is not sufficiently thought upon regarding the formation of duodenal ulcers, and that is the probability of their origin in actual traumatism of the intestinal coat by some hard or irritating substance, such as a piece of bone which escapes stomach digestion. In this way, it seems to me, are best explained those mysterious cases where the first symptoms are those of perforation, and which occur in healthy young adults. Professor Axe of the Veterinary College states, however, in a letter to me upon the subject, that though he has made hundreds of post-mortem examinations upon the carnivora generally he has never observed a death from perforation of the duodenum. While rectal ulcers are not uncommon, all writers on ulceration of the stomach and duodenum agree on the comparative frequency of duodenal ulcers in young males. I can hazard no explanation of this very curious fact, unless it be the

greater frequency of haste in eating and "bolting" indigestible food, but its clinical significance is of the first import. Trier of Copenhagen, who wrote a very comprehensive paper on this subject,¹⁷ collected twenty-six cases of perforating ulcer of the duodenum from the records of the Frederik's Hospital. He also collected a number of cases from other sources numbering altogether 281. He found that the ulcer was situated in the duodenum in 10·7 per cent. of cases, and he concludes that the ulcer most generally occurs about the age of manhood, the average being about forty-two and a third years. A striking similarity has been observed in the Guy's Hospital and the St. George's Hospital estimates. Brinton,¹⁸ in discussing the large number of 654 cases of ulcer of the stomach and duodenum, makes the proportion of stomach ulcer in females over males as 2 to 1. Trier finds that the ulcer of the duodenum is found five times more frequently in males than in females.¹⁹ Perry and Shaw conclude that, excluding burns, duodenal ulcer is three times as common in males as in females. Moore's cases²⁰ show a contrast to those of Brinton, for out of thirteen cases of gastric ulcer reported by him, occurring in a period of twelve years, ten occurred in males and three in females. There was only one case of ulcer of the duodenum, and this was, as usual, in a male, a young man at Lewes about twenty years of age, who for several weeks had severe pains about two hours after taking food. After a meal of pickled salmon very violent abdominal agony came on, and he died collapsed in fourteen hours. The association of ulceration of the duodenum with malignant disease would appear to be very exceptional. Bristowe, in describing the pathological appearance found in a case of general cancer, found a perforating ulcer of the anterior surface of the duodenum, close to a cancerous mass the size of a pigeon's egg. The ulcer seemed to have no direct connexion with the growth, but the latter probably acted by lowering the nutrition of the part. In the list of affections of the duodenum collected by Latham there are three in relation with malignant disease.²¹ Typhoid ulcers in the duodenum and the ulcers associated with anthrax or pemphigus are among the rarities of pathology and need not here be further discussed.

I will now consider the pathological terminations of duodenal ulcers. The ulcer which I am especially considering, and which may well be termed "latent," goes on to rapid perforation and death. Ulcers which are more chronic in their course may exhibit a large number of different terminations and conditions. In a considerable number of cases the ulcer erodes into the pancreas and some large vessel, the patient dying from hæmatemesis. This is a peculiarly common termination of the duodenal ulcer after burns, and most of our museums contain specimens to illustrate it. Duodenal ulcers may cicatrise and the gut recover its normal functions. On the other hand, the calibre of the bowel may be seriously lessened and contracted. Thus Lange²² relates the case of a woman who, after suffering from great mental troubles in digestion disturbances, passed blood in the stools and exhibited symptoms of gastric ulcer, for which she was treated. Eight years after she was operated upon for stricture of the pylorus, as she vomited constantly and had a dilated stomach. The pylorus was normal, but the duodenum was so narrowed about an inch from the pylorus as barely to admit a lead pencil. The stricture was divided and stretched and the patient made a good recovery. When a chronic ulcer of the duodenum threatens to perforate such matting and condensation of the tissues may surround it that the appearance and symptoms of cancer are closely simulated. Billroth is said to have excised the pylorus for cancer when simple ulcer was really present. A specimen of ulcer of the duodenum, where the symptoms closely resembled cancer, occurring in a man aged thirty-six years, is related and described by Gairdner.²³ Stricture of the bile-duct with persistent jaundice caused by the cicatrization of chronic duodenal ulcer is sufficiently well known not to need further mention here. An exceptional association of stricture of the duodenum after cicatrised ulcers is the formation of hernial-like pouches in the immediate vicinity. Specimens of this pouched condition of the bowel have

been exhibited and related by Charlewood Turner.²⁴ He attributed the conditions found to spasmodic contractions of the bowel in the vicinity of the stricture. I have already referred to the fact that tuberculous ulcer of the duodenum is considered rare. A case is, however, related by Murchison,²⁵ where a simple ulceration of the duodenum was followed by tuberculous mischief in the lungs. Two of the cases from the St. George's Hospital post-mortem books are noted to be in association with tuberculous ulceration into the portal vein with profuse hæmatemesis and death is an exceptional termination, noted by the late Dr. Habershon.²⁶ Perhaps the rarest termination of duodenal ulcer is a communication with the colon. Murchison²⁷ speaks of this very exceptional condition, and a case of it is related by Sanderson²⁸ in the person of a man aged thirty years, who was admitted into the Middlesex Hospital complaining of excessive pain in the epigastrium and vomiting a brown pultaceous liquid. He had had four similar attacks with severe pain after meals. The ulcer in the first part of the duodenum was found to communicate with the colon.

This brief consideration of the pathological terminations of duodenal ulcer will serve to illustrate how various must be the clinical symptoms they present, according to whether adjacent vessels, nerves, or viscera are implicated. A conjectural diagnosis is usually only warranted, and clinically it is probably impossible to distinguish them from pyloric ulcers unless such symptoms as obstructive jaundice or the pain coming on some two or three hours after food should point to the duodenum. Ulceration of the duodenum may be exceedingly chronic. Thus Arnold in the Boston Medical and Surgical Journal²⁹ reports the case of a man who for six or eight years had suffered from such symptoms as epigastric pains, cramps, nausea, and vomiting. His meals were retained without pain, but about four hours later he used to have pain and vomit. If nothing was eaten he would occasionally vomit a quantity of whitish sour liquid. Hæmatemesis with blood in the stools preceded his death, and an ulcer was found in the first part of the duodenum, eroding the pancreaticoduodenal artery. The hæmorrhage in the stools and in the vomit may readily give rise to an erroneous diagnosis. Mr. Leopold Hudson of the Middlesex Hospital informs me that he performed a necropsy on a man aged forty-two years in the year 1889. This patient had suffered during life from repeated intestinal hæmorrhage, which was believed by some eminent physicians to be due to cirrhosis of the liver. At the post-mortem examination the liver was found to be normal, as was also the stomach; but on the anterior wall of the duodenum just beyond the pylorus a large solitary ulcer was found. The floor was formed of very little more than the peritoneal coat, the edges were clean cut, and the open mouth of a small artery was apparent. There was no appreciable thickening of the surrounding tissues, and there were no adhesions. As regards the treatment of these more chronic cases of ulcer of the duodenum, when medical measures fail it becomes a question whether an exploratory abdominal section should not be performed. Thus a communication may be made between the dilated gall-bladder and the small intestine when the duct is obstructed by a cicatrised ulcer. The following case, related by Codivilla,³⁰ shows that chronic duodenal ulcer accompanied by distressing symptoms is amenable to surgical treatment. A man aged forty years had for fifteen years suffered with pain in the epigastrium coming on five or six hours after dinner and attaining its maximum during the night. There was also daily vomiting, the vomited matter containing acid and bile and blood. Blood was also passed per anum. Every variety of medical treatment had been tried without avail. At the urgent request of the patient an operation was performed. No lesion was found in the stomach, but two fingers' breadth below the pylorus the duodenum was transformed into a hard mass five centimetres long with numerous adhesions. A coil of the jejunum was picked up and sutured to the stomach. The patient recovered well and increased in weight. Five months afterwards he was able to resume work. He still notices a dragging sensation at the situation of the scar and only then has vomiting, but he has vomited

no more blood. Codivilla claims pri-ri-y or treating duodenal ulcer in this way, and points out that gastro-jejunostomy gives the portion of diseased bowel rest and lessens the dangers of perforation or hæmorrhage. But few cases exhibiting chronic symptoms will probably be treated by the surgeon, though the excision of a chronic ulcer and suture of the bowel are obviously well within the range of modern operators.

The symptoms and diagnosis of the acute perforating ulcer must next engage our attention. In a considerable number of cases the ulcer is absolutely latent, resembling gastric ulcer in this respect. A patient is suddenly seized with agonising abdominal pain, rapid tympanites ensues, and he dies in eighteen or twenty-four hours in profound collapse. There may or may not be vomiting. In other cases there is a tendency towards encysting of the extravasated material and the formation of a subdiaphragmatic abscess. In the majority the symptoms are primarily epigastric or in the right hypochondrium, and this, if it can be clearly elicited, is a diagnostic point of the first importance. In a certain proportion of cases the patient will tell us that he has had similar attacks before, or has had pain and vomiting some hours after meals, again drawing attention to the epigastric region. There is one source of error here. When the intestine is perforated the patient often refers his pain to the patch of peritoneum first inflamed by the contact of the septic fluid. Thus it happens that in a perforation of the cæcum the pain may be attributed to the centre of the abdomen, and in perforation of the duodenum the extravasated contents, flowing towards the pelvis, may first inflame the peritoneum in that locality. A case is related by the late Dr. Barclay³¹ in which it is expressly stated that intense pains occurred on pressure, and were referred to the lower part of the abdomen, and the same point is observed in one of the cases I have related. The violent colicky pains attendant upon perforation of these ulcers render the case very likely to be mistaken for lead colic, especially when they occur in the person of a painter. Thus a case is related by Hadham³² where a painter aged fifty-six years was admitted into St. George's Hospital suffering from violent abdominal pain. He was writhing about, but pressure gave him slight relief; and he had a well-marked blue line on the gums. He was treated for lead colic, but vomited several times, and died fourteen hours after admission. At the post-mortem examination a small clean-cut ulcer was found on the anterior surface of the first part of the duodenum. In these cases the progressive abdominal distensions and vomiting, and the usual signs of grave abdominal mischief should warn the practitioner, but the mistake is one that may readily be made. In like manner confusion may arise between perforation and intestinal obstruction. The distinctions between these conditions are discussed by numerous writers, and I would now content myself with only pointing out the primary importance of getting a sense of fluctuation per rectum, as indicating free fluid in the pelvic cavity. In perforative peritonitis occurring suddenly in either sex with a clear history of epigastric or right hypochondriac symptoms, as previous pain and vomiting, or primary occurrence of the pain about the epigastrium, with tenderness on pressure, the perforation is likely to be in the duodenum in males or near the pyloric end of the stomach in females; and in such cases it seems to me best to make an incision over the affected area. The character of the fluid that escapes may give most important aid. In perforations of the cæcum the pus is intensely foul and the puffs of gas which escape distinctly feculent. In ulcers of the duodenum this would probably not be the case, and though one can hardly argue from two instances the cases I have related show the absence of any feculent smell or odour in the abdominal contents. This may prove to be a valuable diagnostic sign in the future, and I would here draw prominent attention to it. The reaction of the fluid in the peritoneal cavity should of course be acid in cases of perforation of the first part of the duodenum, but the peritoneal exudation must be excessive and would soon neutralise any acidity, so that this test will not stand universal adoption. Nevertheless, acid fluid was found in one of the Guy's Hospital cases related by Perry and Shaw. A word must here be said concerning the researches into the diagnosis of intestinal perforation by Senn of Milwaukee.³³ This authority points out that if the stomach be distended with hydrogen gas and a perforation exists, the gas passes

into the peritoneal cavity, distends it, and the liver dullness disappears, which he considers diagnostic. I would point out that disappearance of liver dullness is not unknown in excessive tympanites, and that therefore I can hardly assign the same weight to this test as expressed by the distinguished American surgeon. The escape of bubbles of gas on pressure when the abdomen is opened may lead one directly to the source of perforation. This symptom was of marked aid in the case related to the Medical Society of London last year by Mr. Percy Dean, and in which that surgeon demonstrated the feasibility of resection of a duodenal ulcer and suture of the bowel, his patient recovering. Similarly Mr. Pearce Gould related a case at last year's meeting of the British Medical Association where a young woman aged twenty years, after a meal of fruit, was seized with severe pain in the right hypochondrium, with subsequent collapse and vomiting. Twenty-six hours after the onset of acute symptoms he operated, and as there was nothing to indicate the seat of the perforation he opened the abdomen below the umbilicus. Gas and acid fluid escaped. So, having rapidly explored the generative organs and vermiform appendix, Mr. Gould cut down on to the stomach above the umbilicus and immediately exposed a small perforation in the duodenum. This he excised, carefully sutured the wound so made, and having flushed out the peritoneal cavity closed the laparotomy wounds, leaving a glass drain in the lower incision. At the close of this operation the patient was in a state of profound collapse, being very nearly pulseless at the wrist. Thirty-two ounces of saline solution were injected into one of her veins, and he had the satisfaction of seeing this collapse pass off to a considerable extent. Nevertheless, nine hours later she died; and at the post-mortem examination he found that the duodenal suture was firm, that no water escaped from the bowel even under considerable pressure, but that there was general peritonitis. "It was no satisfaction to me," Mr. Gould remarks, "no benefit to my patient, that the suture was firm, while her peritoneum had been left foul. It was only a surgical illustration of the vulgar proverb which cautions us against closing the stable-door when the steed was stolen." I have made in the post-mortem room of St. George's Hospital a series of observations on the best position for placing the incision in the abdominal parietes in supposed mischief about the duodenum. The incision in the median line does not give free access to the right hypochondriac region, and one can easily conceive that it might be difficult to detect and to suture a duodenal ulcer through it. In like manner an incision in the right linea semilunaris appears to be too far external to give access to the pylorus and first part of the duodenum. A vertical incision four to five inches long, according to the thickness of the parietes, from the right eighth cartilage downwards, two inches to the right of the median line, is in the majority of instances over the duodenum. Such an incision enables one to explore the pylorus, duodenum, gall-bladder, and under surface of the liver, and through it an ulcer on the anterior surface of the duodenum could be easily reached. I would draw attention to the immense advantage of holding asunder the margins of the abdominal wound in this and similar proceedings by means of stout silk loops passed through the parietes. By this means exploration can be most thoroughly managed, and the manœuvre greatly facilitates the return of distended bowel, I would also venture to express my opinion that the secret of success in these cases is the complete after-cleansing of the peritoneal cavity. Mr. Gould strongly expresses himself regarding this point, but I cannot now enter into this subject beyond expressing the belief that our present methods are not sufficiently complete and elaborate.

In conclusion I would draw attention to the following points, which seem clear from a perusal of the published cases of this affection. 1. That in perforative peritonitis there is nothing to point to the duodenum as the site of lesion unless it is clearly made out that the onset of pain was in the epigastrium or right hypochondrium; or that previous epigastric symptoms, as pain and vomiting, had occurred. Great care should be taken over the investigation of this part of the history, which is most vital and important. 2. That, considering the frequency of duodenal ulcer in males, the possibility of this affection should always enter the minds of surgeons who are called to a case of perforative peritonitis occurring in a man. 3. That the non-feculent and sometimes acid nature of the

extravasated fluids and gas may serve as a most important diagnostic aid, and the incision may be made small as an exploratory effort only until this vital point is made clear. When once the surgeon has made up his mind that the exudation is non-feculent, and especially if it be acid, the region of the stomach and duodenum should be explored without loss of time. The nature of the fluid is a matter for future observation. 4. In severe shock it is perhaps well to wait for a few hours. The peritoneum must be most energetically washed with warm water, and a drainage-tube placed in the pouch of Douglas would probably be of utility.

Cavendish-place, W.

TOBACCO AMBLYOPIA.¹

By A. MAITLAND RAMSAY, M.D., F.F.P.S. GLASG.,
SURGEON, GLASGOW EYE INFIRMARY; LECTURER ON EYE DISEASES,
QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW.

THOUGH it has long been known that the excessive use of tobacco is injurious to the eyesight, it is only within comparatively recent years that the visual disturbances arising from the toxic effects of nicotine have been carefully studied and their clinical features accurately recorded. Many of the older ophthalmic surgeons² used to ascribe to tobacco poisoning a large number of obscure forms of disordered or suspended visual function, in which the etiology of the disease should have been assigned to some entirely different cause. The somewhat wholesale condemnation of the use of tobacco to which this idea gave rise has still a widespread currency, and by those who have the slightest thought that they smoke in excess no question is more commonly put to their medical attendant than, "Is it tobacco that is doing me harm?" or "Must I give up smoking?" Though the existence of amblyopia from this cause can no longer be doubted the disease must, considering the large number of people who habitually use tobacco, be admitted to be of comparatively rare occurrence, nearly all the cases that come under observation being more or less complicated by free indulgence in alcohol. As to the frequency of nicotine amblyopia it is, therefore, difficult to arrive at very accurate conclusions; it probably, indeed, varies in different countries, and is in large part regulated by the habits and customs of different nations. Just as there are people so constituted that even excessive indulgence in tobacco and strong drink has on them no appreciable effect, there are others in whom, owing to some peculiar idiosyncrasy, even the most moderate use of either produces marked toxic disturbances. Of all the cases observed by Horner³ during a period of two years 0.7 per cent. were due to abuse of tobacco and alcohol; while Galezowski⁴ found 1 per cent. in a total of 36,000 patients. Though the introduction of the ophthalmoscope shed new light upon the site and the anatomical cause of many cases formerly grouped under the general names of amblyopia and amaurosis, yet amblyopia arising from the abuse of tobacco and alcohol presents in its earlier stages no ophthalmoscopic picture that can be regarded as pathognomonic. In such cases, indeed, the contrast between the gravity of the symptoms and the absence of any marked lesion that ophthalmoscopic examination can detect is one of the most striking characteristics; and our knowledge has been derived rather from careful examination of symptoms, more especially of the limitations of the visual field and of defects in the colour sense, than from any changes that can be detected in the optic nerve and retina.

In the following case, first seen in December, 1888, we have a good example of amblyopia due clearly to the toxic influence of tobacco. A man aged fifty-nine years complained of dimness of vision in both eyes. Though the defect had only attracted serious attention somewhat suddenly about eight weeks before, I was able to elicit the fact that for twelve months he had had difficulty in recognising the features of friends unless they were quite close to him. He had become less and less able to read small print, and found that no spectacles he could get brought about any

improvement. When he was walking along the street at night the flame in a gas lamp would seem suddenly to go out, but would again become visible as he approached nearer, while another then seemed to disappear. The flame of the lamps always appeared to him to be of a blue colour. The defect in vision was as pronounced in one eye as in the other, and when I saw him he could barely read the letters in No. 19 Jaeger, and his vision for distance was not equal to $\frac{1}{8}$ by Snellen's test types. He had never suffered from any pain in his eyeballs, and there was no tenderness when the ball was pressed backwards into its socket. The intraocular tension was normal, the movements of the eyeballs were perfect, and the pupils were of equal size and responded normally both to the stimulus of light and in the act of convergence. By careful examination it was demonstrated that the dimness of sight was wholly confined to the central area of the field of vision, and that when the confines of this dull area were reached the vision of the other parts of the field was normal quite up to the periphery. In the affected central area colour sensation was also entirely absent. Ophthalmoscopic examination revealed no lesion to account for the intensity of the symptoms, and beyond the fact that the left optic nerve was rather paler than the right there was nothing to be noted. The patient (a foreman in a large printing establishment and most regular in his attendance in the workshop) was a strong, healthy-looking man, who had never suffered from any other illness than some slight digestive disturbances. He had, however, in consequence of domestic difficulties been subjected for many months to much mental anxiety, and he himself attributed the onset of his defective vision to "indigestion and worry." Though he had begun to use tobacco when only nine years old, and had smoked regularly thereafter, he was not conscious of having ever suffered in any way from this cause, even the sickness usually attendant on the first experiences of nicotine having been in his case remarkably slight. For more than forty years he had smoked on an average about four ounces of black twist every week; but of late, though for no particular reason, the quantity had been less—probably about three ounces. He invariably smoked before breakfast, but as he was always regular with his meals that was the only time when he smoked with his stomach empty. He had always been very abstemious, and for the last fifteen or sixteen years had never tasted alcohol. The patient was advised to abstain from the use of tobacco; but finding that impossible he substituted a very light quality for the black twist, and limited the quantity to two ounces a week. A dose of one-sixteenth of a grain of bichloride of mercury with five grains of iodide of potassium, to be taken after meals, was prescribed for him, and when he was seen again after four weeks' treatment he reported that for more than a fortnight there had been a progressive improvement in his eyesight. Tested by Snellen's types, it was found that the visual acuity was now $\frac{1}{2}$ of the normal instead of $\frac{1}{8}$, as at first. Aided by glasses he could read moderately large print; and although he could now distinguish blue and yellow, yet in the central area of the field of vision sensation for red and green was still absent. The former appeared to him "like silver," while the latter "glittered like gold." When, however, he was shown a gold and a silver coin he was unable to distinguish the one from the other until he had felt the difference in weight. He had by this time no difficulty in counting all the street lamps. There was no change in the ophthalmoscopic appearances. Caution in the use of tobacco was again enjoined, and for the biniodide of mercury a Plummer's pill at bedtime was substituted, with a quinine and strychnine tonic before food. After a two months' holiday in Ireland—during which he smoked regularly, but also took his medicine steadily and kept out of doors as much as possible—his vision was found to have improved to $\frac{3}{4}$ of the normal. He continued to take a tonic mixture containing nux vomica, and six months after the date when I first saw him he resumed his duties and was able, although with a little difficulty, to read proof sheets as formerly. At the first glance red and green spots still appeared to him to have a metallic lustre, but after he had looked at them for a few seconds the colours became quite distinct. He had now not the slightest difficulty in at once distinguishing between a sovereign and a shilling. His own comment was that he could now see the colour in a person's face and in the skin of his own hands, whereas three months before he could distinguish no ruddy tint, the appearance presented to him being "just like that of a dead person," and as he walked along the streets the faces of the passers-by wore a

"deathly pallor," and he was "unable to distinguish their eyes." The patient continued regularly at work till May, 1893. While he still abstained from alcohol, he had begun to use tobacco almost as freely as he had been doing before his illness, although the quality was not so strong. As his sight was again beginning to fail he gave up his situation. He found that his vision varied greatly and was uncertain—"some days he could not see well, at other times he was able to read well enough." He came under treatment again in September, 1894, when it was found that his visual acuity varied between $\frac{1}{4}$ and $\frac{1}{2}$ of the normal; there were slight central amblyopia and partial colour defect—at one time he could tell all the colours, while at others he hesitated with red and green, and when the dyschromatopsia was most pronounced his vision was least acute. It was now noticed, however, that there was a slight peripheral contraction of the visual field, the optic discs were pale, more especially in their outer two-thirds, and very well defined in outline, the retinal arteries were somewhat reduced in calibre, but the veins were of normal size. Strict injunctions were again given as to the use of tobacco, and a mixture containing nux vomica and iodide of potassium was prescribed. After a fortnight's treatment the power of vision became steadier, but it has not yet (November, 1894) improved up to the point it had reached after his first attack.

I have recorded this case in full because from many points of view it is typical and illustrative, and because I have had an opportunity of observing it regularly from the beginning. First of all, it is a pure tobacco case, as for nearly twenty years the patient has almost entirely abstained from alcohol, and it proves that recovery up to a certain limit can take place even although the patient continue all through to use tobacco of light quality and in reduced quantity; but it also proves that when the use of tobacco is unduly increased a relapse will follow, while the addition of a concentric contraction of the visual field to the group of symptoms originally noted suggests that, as a result of the prolonged irritation of the tobacco, what was at first a mere functional disturbance has become changed into an organic disease of the optic nerve. In cases of nicotine amblyopia the patients are usually men of from forty to sixty years of age who have used the stronger forms of tobacco for a number of years.⁵ The onset of the symptoms, though sometimes sudden, is usually so slow and gradual that patients have difficulty in determining the exact date of commencement. Those affected, unless suffering from debility arising from some other cause, usually present a strong healthy appearance; but the perception of the peculiar odour mentioned by Mr. Doyne⁶ may sometimes direct attention to the true nature of the case. They rarely admit ill-health; but questioning brings out that for some time before the dimness of vision was first observed they had been worried and sleepless, and had suffered from loss of appetite and digestive disturbances. In most cases the patients say that they have recently been smoking less; and Förster⁷ believes that tobacco is not so well tolerated during the second half of life as during the period of full vigour. All experience, too, goes to prove that those who are well nourished, sleep well, and in general take life easily are able to use much larger quantities of tobacco than those who are not so favourably circumstanced, and that there are some who as a result of congenital predisposition are unable to use even small quantities without suffering from symptoms of nicotine poisoning. Workers in tobacco factories who neither smoke nor chew seldom suffer from amblyopia, and van Millingen⁸ of Constantinople affirms that he has never met with a case among the Turks. He thinks this is accounted for rather by their smoking cigarettes than by their using mild tobacco, and comes to the conclusion "that tobacco poisoning is only possible when nicotine in solution is brought into contact with the mucous membrane of the mouth and swallowed." The poisonous effects may, however, as suggested by Dr. Lauder Brunton,⁹ rather be produced by the volatile alkaloids formed during the combustion of tobacco. As much stronger tobacco can be smoked in the form of a cigar than in a pipe, cigar and cigarette smokers are probably more exposed to

⁵ There are exceptional cases where visual defect showed itself very shortly after smoking or chewing was begun. Some few cases in women are also reported. (See Transactions of the Ophthalmological Society, vol. vii., 1887.) The youngest of my own patients was a man twenty-eight years of age, who had for several years smoked eight ounces of strong black twist every week.

⁹ Book of Health, p. 254, 1884.

the risk of nicotine poisoning than others, and possibly their comparative immunity arises from the fact that, "according to Vohl and Eulenberg, the tobacco which is smoked in a pipe yields a very much larger proportion of volatile bases, and especially a larger quantity of the very volatile and stupefying pyridine, while in a cigar little pyridine and much collidine is formed, the latter being less volatile and active than pyridine." In support of this theory I may add that I have never seen a case of tobacco amblyopia in a patient who chewed but did not smoke. In my own experience the patients who suffered most were those who had been in the habit of smoking on an empty stomach the first thing in the morning, in fits of sleeplessness during the night, or during the day in place of a meal. Persons are then in the best condition for absorbing the nicotine or combustion products into their blood, and in the worst condition for resisting their injurious influence. Patients complain that in bright light they are easily dazzled, and that a whitish or yellowish mist rises like a cloud in front of their eyes and prevents them from seeing clearly. In the after part of the day, when the sun is not so strong, this sense of dazzling disappears and vision improves, or at least seems to do so.¹⁰ By-and-bye small print can be read only with difficulty, and stronger spectacles are procured but with no good result, while at last even the inability to read ordinary-sized type becomes quite decided. The dimness of vision is as pronounced in the one eye as in the other, and this symmetry, being a strikingly characteristic symptom, is of great value in distinguishing amblyopia due to tobacco or other toxic cause from diseases of the choroid, the retina, or the optic nerve, in which both eyes are also frequently affected, but where the diseased condition of the one is, as a rule, much in advance of that of the other. In the Moorfields Hospital Reports for 1886 Mr. J. Hutchinson, jun., describes a case where one eye was attacked six months before the other; and in the same Reports for 1889 Mr. Doyne gives a case of monocular tobacco amblyopia which he had observed in a man aged thirty-eight years. Such instances are, however, very exceptional. The diminution in the visual acuity varies according to the stage of the disease. At first there is simply a general dimness—a diminution of the light sense—but afterwards vision is reduced to $\frac{1}{10}$ or even $\frac{1}{20}$ of the normal. This failure is due to defect in the centre of the field, but of this the patient is not conscious, as he would be if the disease were due to a lesion in the outer layers of the retina. The scotoma then is "negative" or "relative." That the defect is confined to the central, without any contraction of the peripheral, field of vision is in marked contrast to what occurs in atrophy of the optic nerve—for example, in *tabes dorsalis*, where there is progressive contraction of the field from without inwards. In the former the defect may involve only a very small area, and in the latter the greater portion of the field, so that only the central parts round the fixation point remain useful. Yet in the following two cases the interference with vision is very different. The first, a man with the central defect, could hardly see sufficiently to guide himself about, while another patient I had—a sufferer from *tabes dorsalis*—was able, though completely blind in the right eye and with only a small central area of the left remaining, to drive a horse and van through crowded streets. The scotoma is transversely oval and usually extends from the point of fixation to the blind spot, and although remarkably constant in size and shape may occasionally be of larger dimensions and surround the fixation point—the paracentric and the pericentric scotoma of authors. Grenauw¹¹ and others have tried to form a differential diagnosis according to the shape of the scotoma, and claim by this means to be able to distinguish tobacco cases from other forms of toxic amblyopia. It would seem, however, that those variations in size and shape depend more upon the dose and effect of the toxic agent than upon the particular kind of poison. The more profound the amblyopia the larger the scotoma.¹²

¹⁰ One of my patients told me he could always play best at bowls in the evening, because when he played in the sunlight he could not see the "jack" on account of the dazzling in front of his eyes; and another patient, a calman, has assured me that he has less difficulty in distinguishing numbers on doors in the evening than during the day.

¹¹ Graefes Archiv für Ophthalmologie, vol. xxxviii., 1892; see also Hirschberg, Deutsche Zeitschrift für Praktische Medizin, 1878.

¹² In the case of the first patient just mentioned the scotoma extended beyond both the fixation point and the blind spot, and for a considerable but indefinite distance beyond the absolute scotoma a red test object appeared to be brown.

A true pathognomonic sign, however, is that even when a white object can still be recognised in the centre of the field there exists a scotoma for colour—green appears grey or white, pink blue, and red brown, &c. As the disease progresses the colours assume a metallic lustre, and red and green look like silver and gold. Gold and silver coins, however, appear alike. At length, with the disappearance of the power in the region of the scotoma to recognise a white object, all colour sensation disappears, and in the most extreme cases even a candle flame cannot be recognised. The scotoma is now absolute. As, however, the eccentric parts of the visual field are quite normal patients are often unaware of their colour blindness; they see a large surface of red or green with perfect distinctness, but when a small square of colour is employed as a test object the defect becomes at once apparent. It is most marked for red and green, least so for yellow and blue, the latter being in many instances recognised perfectly when the former cannot be distinguished. A patient, a gardener, told me that the first indication he had of failing eyesight was inability to distinguish the red colour of a strawberry. Before the fruit was ripe he could distinguish the berries fairly well, but whenever these became red he failed to see them unless he were looking closely at the plants. For the purpose of roughly estimating the extent of the peripheral field and detecting the presence of any central defect I am in the habit of using a series of small white and coloured metal discs, all of which can be fitted into one handle. Of course, where accurate observations have to be recorded a perimeter must also be employed. In the less severe cases, when the central scotoma is not very pronounced and the visual acuity not greatly reduced, I am in the habit of employing coloured papers (3 in. by 2 in.) pasted upon a sheet of black cardboard. The colours selected are as nearly as possible complementary. On red paper are fixed green dots and *vice versa*. The patient has no difficulty in recognising the mass of colour, but he is quite unconscious of the dots.

In striking contrast to those changes in the visual field just described are the results of ophthalmoscopic examination. In the earlier stages the optic disc may be hyperæmic and less transparent than natural, but in a large majority of instances the ophthalmoscopic appearances are quite normal. As the disease progresses, however, the natural colour of the nasal third of the papilla contrasts with the greyish whiteness of the temporal two-thirds. In extreme cases the whole papilla may assume the appearance of white atrophy; but here, in addition to the central scotoma, there is usually some contraction of the periphery of the visual field. Mr. Lawford¹³ has recorded nine examples in which atrophy of the optic nerves with contraction of the visual field came on in patients who at first exhibited all the symptoms of tobacco amblyopia. Complete atrophy of the optic nerves is exceptional and is only met with in those cases in which the central scotoma is large and absolute and in the late periods of the disease. Although nervous complications—e.g., paralysis of the oculo-motor nerves¹⁴ &c.—are of rare occurrence, it sometimes happens that in complete atrophy symptoms of *tabes dorsalis* become superadded; but it must always remain doubtful how far the tobacco is to be blamed for the onset of such complications. De Wecker¹⁵ has grouped all cases of toxic amblyopia under the heading of retro-bulbar neuritis, but, as Berry¹⁶ suggests, there are good reasons for doubting the existence of actual inflammation of the optic nerve in many instances of tobacco amblyopia. A well-marked case of retro-bulbar neuritis presents points of difference from, and exhibits symptoms which are altogether absent in, an ordinary case of tobacco amblyopia—e.g., pain in movement of the eyes and tenderness when the eyeballs are pressed backwards into their sockets; the central scotoma is not so constant in size and shape; the ophthalmoscopic picture is more often characterised by inflammatory change in the optic disc; the amblyopia is usually more pronounced in one eye than in the other, or the disease may be wholly confined to one eye; and there are often intolerance of light and complaint of aching pain in the circum-orbital region. The presence of the central scotoma is the one common characteristic in all the cases which de Wecker groups together. In position this scotoma corresponds to the area of the retina which is supplied by the papillo-macular fibres.

¹⁶ Moorfields Hospital Reports, 1889.

These, according to the researches of Samelsohn,¹⁷ Vossius,¹⁸ and Bunge,¹⁹ lie at first in the axis of the nerve stem as a cylindrical bundle, but change their shape and position as they pass towards the eyeball, into which they enter as a wedge-shaped bundle on the temporal side of the optic disc. The apex of the wedge is directed to the central vessels. In 1882 Samelsohn demonstrated the existence of an interstitial neuritis which was limited to the fibres of the papillo-macular bundle in their course through the nerve stem from the optic foramen downwards towards the optic disc, and this observation has been confirmed by Nettleship,²⁰ Unthoff,²¹ and others. The inflammatory process leads to proliferation of the connective tissue surrounding the nerve fibres, these suffering compression and ultimately becoming atrophied when the new-formed tissue begins to undergo cicatricial contraction—a pathological process analogous to that which is seen in the liver and kidney in consequence of prolonged irritation from alcohol &c. But in typical cases of tobacco amblyopia the complete recovery which usually takes place, and the fact that on the one hand a single good night with quiet sleep can considerably improve visual power, while on the other hand the colour scotoma can be increased by fatigue,²² is not at all consistent with the theory that the papillo-macular bundle has been actually inflamed. Moreover, the fairly constant shape of the scotoma, its symmetry, and the similarity in the degree of amblyopia in both eyes point rather to the existence of some lesion of a vascular kind than to an interstitial neuritis. From their anatomical position the papillo-macular fibres at the optic foramen, where they enter the nerve stem, are those which are most abundantly supplied with blood on account of the very fine capillary meshwork which surrounds them, and are consequently those that will be most liable to nutritional derangement when any toxic agent exercises an irritating action in their neighbourhood. It is probable, therefore, that in the simpler forms of tobacco amblyopia the directly hurtful action of the nicotine, or of the products of its combustion, produces such a functional derangement of the macular fibres.²³ In severe cases, and more especially in those complicated by alcoholism, anatomical changes in the nerve probably become superadded, and a true retro-bulbar neuritis results. In all such cases, however, in addition to a well-marked and often absolute central scotoma, there is a peripheral contraction of the visual field, and the latter symptom should always be interpreted as indicating the existence of organic disease of the optic nerve, which will sooner or later reveal itself by pallor of the optic disc. Whenever, indeed, in a case of supposed tobacco amblyopia there is found limitation of the peripheral parts of the field of vision, the patient ought to be examined most carefully for any symptoms which would indicate the commencement of disease of the spinal cord—e.g., tabes dorsalis, disseminated sclerosis, &c. As far as my own observations go, all cases of tobacco amblyopia where recovery is not complete will sooner or later exhibit peripheral contraction of the visual field; and if in such cases the alcoholic element be strong, and the patient's environment such as to debilitate and lessen nerve tone, the atrophic changes in the optic disc are prone to become progressive and vision to be correspondingly impaired.

The prognosis is undoubtedly favourable in all uncomplicated cases of tobacco amblyopia provided the patient will give up the use of tobacco. In most instances the promise is readily given, but the intention is not always carried out, and after a short period of abstinence smoking is again begun. The resumption of the old habit may bring on a relapse and prolong the convalescence, and when, as in the first case described, smoking in a modified form is persisted in all through the course of the illness, the recovery of visual acuity is never so complete as it would have been if tobacco had been faithfully abstained from. In every instance the progress is slow, and except in very mild cases, where medium-sized print can still be read, six or nine months or even longer are required before the patient is able to use his eyes for near work. When the central defect is absolute it

is always wiser, before giving a definite prognosis, to test carefully to ascertain the existence of any concentric limitation of the visual field, and, when that is present, to give a guarded opinion until sufficient time has elapsed to permit the efficacy of the treatment employed to be tested.

In the treatment itself the first step should always be the prohibition of the use of tobacco and alcohol. Complete abstinence is to be desired in all cases, because it must ever be borne in mind that the result is determined not so much by the actual quantity of tobacco smoked or of alcohol consumed, as by the capability of the patient for resisting their injurious influence. Some patients affirm that they see better when they are using alcohol than when they abstain, but the wish is mostly father to the thought, and the fact remains that true inflammatory changes in the optic nerve are much more likely to supervene upon already existing functional disturbances in those addicted to over-indulgence in alcohol than in those who rigidly abstain from its use. It ought to be remembered, however, that with many tobacco acts as a laxative, and that when its use is suddenly discontinued constipation and digestive disturbances are apt to follow. This difficulty, however, can easily be overcome by the use of some aperient medicine. In the early stages, when, although it may not be visible by the ophthalmoscope, hyperæmia of the optic nerve probably exists, the eyes ought not to be used for near work, and the dazzling of which so much complaint is made can be greatly lessened by the use of dark glasses, while the administration of mercury and iodide of potassium gives good results. After six or eight weeks the mercury may be replaced by full doses of nuxvomica. Some recommend the hypodermic injection of strychnine, but no special advantage is to be gained by the subcutaneous method of administration, because the good effects that follow the use of nuxvomica and strychnine depend more upon their general tonic effects than upon any special action which they may exercise upon the optic nerve itself. After recovery is fairly complete a quinine and strychnine tonic may be taken with advantage for many weeks, and if the patient be anæmic some ferruginous preparation and cod-liver oil, malt extract, &c. ought to be taken after meals. In addition, everything ought to be done by means of nourishing food in full amount, and of restful holiday with freedom from worry, to promote the patient's comfort and improve his general condition.

Glasgow.

ON THE EVOLUTION OF THE SYPHILITIC POISON IN MAN AS AT PRESENT OBSERVED IN ENGLAND.

BY HENRY LEE, F.R.C.S. ENG.,
CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

As a rule the symptoms of secondary syphilis are confined in the first instance to the skin and mucous membranes. If the surface be in good condition and its secretion be not checked it is probable that the disease will eliminate itself through the skin without affecting any other parts. If, however, the secretion from the skin gets checked, according to my experience internal parts may become involved. The bones appear to be the structures most frequently affected, but it is not always clear whether it is the disease or the remedy which is most to blame in these cases. Disease of bone is, as a rule, a late symptom, and it will generally be found that the patients suffering from it have taken quantities of mercurial pills during the time they were exposed to cold air. In a case admitted into King's College Hospital, however, if the history can be relied upon, a node on the frontal bone was the first symptom of constitutional disease. The influence upon internal parts is sometimes developed very suddenly and disappears with appropriate treatment. A patient under the influence of mercury for syphilis rode through a brook whilst hunting. He became paralytic and was completely restored under a regulated course of calomel baths. In rarer instances the early symptoms of bone disease accompanied by nervous affections may be permanent. A wonderfully strong and well-developed man, who from his occupation was necessarily exposed to the weather, was seized while under the influence of mercury with hemiplegia of the left side. A portion of bone was removed from the right

²² Horner speaks of a fatigue scotoma, "Ermüdungskotom."

²³ In its earlier stages tobacco amblyopia seems to bear a very close analogy to a form of tinnitus which is said to follow over-indulgence in tobacco. Dr. Woakes has advanced the hypothesis that the noises in the head are due to a "hyperæmic state of the circulation of the middle ear."—Deafness, Giddiness, and Noises in the Head; p. 97, 1879.

temple by means of a trephine. The patient died from inflammation of the brain: A piece of dead bone an inch in length and confined to the internal table was found within a couple of lines of the opening made by the trephine. The preparation is in the museum of St. George's Hospital. Another patient had necrosis of the whole thickness of the frontal bone extending some two inches in each direction. A portion in the centre was removed by a trephine. This was deeply honeycombed on its internal surface. A thick layer of plastic lymph covered the surface of the dura mater. A drawing of the case is preserved. In two other cases the patients lost a large portion of the outer table of the frontal bone without any corresponding nervous symptoms. In later cases patients who had lost portions of bone from the nose retained their nervous symptoms until death. One of these had epileptic fits; the other, who had been under the care of Ricord in Paris, never lost the sensation of having wool in his mouth. One patient came from India with undoubted secondary syphilis and with necrosis of portions of the upper maxillary bones. With the exception of the two first cases these all came under my observation at a late period, having presumably been under the usual treatment by mercury internally whilst exposed to the weather. These are typical cases, and there can, I think, be no doubt that the diseased action, which naturally would have its evolution on the skin, was transferred to the deeper structures.

In contrast to these it has never occurred to me to see the bones affected where the calomel bath has been carefully used from the commencement. The remedy meets the disease where it is naturally developed, and the excretion from the skin is increased and favours the elimination of the disease. It is through the skin that the natural cure takes place, and it has very seldom indeed happened to me to witness any recurrence of syphilitic symptoms after a persistent and careful use of the calomel bath for two or three months.

What has been said with regard to disease of the bones is equally true with regard to other internal organs. I am acquainted with the cases of six patients who from professional engagements or other causes preferred to be treated by mercury internally while going about exposed to the weather as usual. In all of these very grave internal complication arose, from which none of them ever really recovered. In one case the patient, himself connected with a bath establishment, took the calomel baths for a week or two, and then elected to try other treatment. In the course of a very few months I was grieved to hear of his death. In a second case the patient, who advocated the internal use of mercury, and told his patients that during its use "the more they were in the open air the better," himself died from secondary syphilitic deposit in the liver. In a third case there was hemiplegia, and in a fourth paraplegia. In a fifth case the patient contracted syphilis in attending a midwifery case, and from this he died. Again, in contrast with such cases and a large number which have recently been recorded, I may with truth say that I know of no instance where the calomel bath has been properly used during the early stage of the disease in which any serious internal complication has arisen.

In close connexion with this subject is the question of the lapse of time that ought to intervene between a syphilitic infection and marriage. I have always held that no period can be specified. If the disease has become ingrained in a patient's constitution, and he has become, as often happens, proof against any further mercurial action, no length of time will render him perfectly safe. If, on the other hand, he has gone early through a proper course of mercury, he may, in my opinion, marry at any time. In a number of cases I have given my sanction to a patient marrying under these circumstances, and have as yet had no reason to regret my opinion. In one case a rash appeared after marriage, which was undoubtedly syphilitic; this, however, disappeared with some additional treatment, and no harm happened.

Savile-row, W.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon (the 5th inst.). Sir James Crichton-Browne presiding. The following were elected members:—Mr. Henry Irving, Mr. Henry Perigal, Mrs. Slingby Tanner, Mr. Ernest H. Fry, Mr. Thomas Muir, Mr. Harold Smith, and Mr. W. S. Smith. The special thanks of the members were returned to Mr. George Matthey for his donation of £50 to the fund for the promotion of experimental research at low temperatures.

INFLUENZA TOXÆMIA OF 1895 (FEBRUARY TO MARCH), WITH SPECIAL REFERENCE TO ITS CARDIAC MANIFESTATIONS AND PULMONARY COMPLICATIONS.

By ARTHUR W. B. WARDE, M.D. DURH.

THAT "each outbreak differs from another" has become a popular saying, and a true one. It is a saying specially true of the present epidemic, which has been answerable for a large number of peculiar heart and lung affections. It is remarkable that pure lobar pneumonia has been practically absent in my practice, whereas about thirty cases of bronchopneumonia, many of hypostatic type, have come under observation—some mild, some severe. The short duration of a high temperature, the limited number of sudden acute attacks, and the lengthened duration of a slight rise of temperature are very characteristic of this year's influenza. I think no one can doubt the presence of a distinct toxæmia—acute, subacute and abortive, brief or tedious in duration. I believe in all varieties the symptoms are those of septic intoxication. Although not conversant with bacterial life and growth, I venture to state my belief that the train of symptoms comprising influenza and its complications is produced by the absorption of a poison—be it simply chemical or alkaloidal (ptomaines)—into the circulation—a poison manufactured by bacilli multiplying on the mucous membranes of the respiratory and alimentary tracts. It will be apparent to many that I have in mind the present day teaching with reference to the absorption of toxins in diphtheria. The poison in its circulation would seem to act directly on the blood, causing corpuscular destruction; directly or indirectly on the vessels, tending to produce endocarditis, endarteritis, and stasis; and indirectly on the whole nervous system, or selecting one part of this, such as the vagus nucleus and nerve, or that combined with the sympathetic ganglia. The oft-occurring slow pulse, the subnormal temperature (following), the vomiting, and possibly the hypostatic type of pulmonary disease seem to point towards a special preference for the vagus and sympathetic systems.

Difficulty is met with in diagnosing influenza when the attack has aborted, or at least when the acute stage is over—an important question, in that it concerns the signing of certificates for illness. The bright, suffused, and watery eye; the cold, clammy, perspiring hands and sometimes feet; the tremulous condition (occasionally present) of arms, tongue, and body—are all useful as a guide. In a very large number of cases, if uncomplicated, the temperature will be found markedly subnormal. Very frequently an intense redness in the fauces will be found, and thereby hangs a tale, for when, in addition to this redness, the smell of alcohol is strong, it is quite impossible to tell absolutely whether a patient is suffering from the effects of acute alcoholism or from the after-symptoms of influenza. A very slow pulse is to me almost pathognomonic of influenza when it exists, but one cannot be certain, as a rule, of its absence before the attack. This year I found very few marked cases in children. Among very young children two of them appeared to be at death's door—in a word, literally poisoned nearly to death—and yet they proved to be convalescent within twenty-four hours. As in former epidemics, again this year there was an apparently simultaneous outbreak in many parts of the country. The fact is, however, that in December a very severe type of catarrh—in reality, probably influenza in a mild form—was prevalent in this town with cases of true influenza occurring every now and again during that month and the following months of 1895. I believe it to be a fact that this new epidemic was simply deferred in its development by the rigour of our winter. With the thaw medical men and plumbers had ample employment.

I was able to trace the very gradual growth of a town epidemic in Newcastle-on-Tyne during the winter of 1889-90. When our first great outbreak in modern times occurred early in January, 1890, I was able by means of my official visiting list and case-book to trace back, right into the first or second week of November, 1889, a fair number of what I recognised to be cases of true influenza—cases by which at the time I was greatly puzzled. In passing I may add that I firmly believe that influenza was epidemic in North Devon during

the winter 1887-88, and especially during February, 1888. Possibly catarrh may precede influenza, as cholera is said to be fore-heralded by epidemic diarrhoea.

I should be glad to know the opinion of the profession on a few points of interest. Is not influenza really endemic, accounting for the obscure "febriculas" of the past? What is its relationship to ordinary or common catarrh? Are the two of one birth? Are they not one and the same thing? In catarrhal subjects does not influenza take the place of their usual seasonal catarrh? In fact, are the two not mutually interchangeable? Are not common catarrh and influenza, each varying in type and sequelæ, responsible for the symptoms of what is called "rheumatism"? That "rheumatism" may be the result of other causes, such as cold and wet, scarlet fever, septicæmia, pyæmia, and gonorrhœa, I do not deny, but take it that in all some kind of blood poisoning occurs to produce the symptoms called rheumatic. Dr. Newsholme's *Milroy Lectures on the Natural History and Affinities of Rheumatism* prove its occurrence in epidemic form in certain years and suggest its dependence on some definite disease, which may, in fact, be catarrh or influenza. Although this year has shown me only one joint affection following influenza, I have met with others during former epidemics—*post hoc vel propter hoc*—and the frequency of the cardiac complications to my mind suggests more than a casual connexion between influenza and rheumatism.

Influenza affecting the heart.—Judging from my own experience, the sum total of hearts damaged by this epidemic must be enormous—a truly alarming state of affairs, unless the damaged valves recover so as to show no trace of the mischief. Altogether I came across about twelve cases, all those of women excepting three. In the notes given below I have omitted three cases as being only suspicious, although conclusive enough to myself. Women are especially liable, as also are young adults of both sexes. In some of the cases—possibly in most—a previous catarrh (or influenza) had existed before the occurrence of the actual symptoms for which I was summoned, but was not of such importance as to necessitate lying up. Probably the catarrh was influenza, the actual need for medical advice depending on the complications which followed in the lungs or heart, or in both. In a few possibly the affection was developed at once. In two cases the heart was dilated when first seen, the murmur developing later. The cases are singular for their close resemblance. In all the aortic valves were at fault—in one, possibly, the mitral as well. A slow pulse was sometimes present as soon as the temperature was lower, varying in frequency from 50 to 64, being large, sudden, and bounding, but a full pulse rather than an empty one. A thrill was present on two occasions. The heart was dilated in all cases, the apex beat being felt in the normal interspace in the nipple line or just outside, with cardiac dullness extending often to the mid-sternum and even to the right border of the sternum. The dilatation several times disappeared or lessened at once, but remained in some. A double aortic murmur was present in one case; in the others there was a systolic aortic murmur, usually heard well over the fourth and fifth cartilages near the sternum on the left side, but heard quite as well usually up the chest as far as the aortic area, and even into the right side of the neck, and the left, too, to a less extent. My note is deficient as to the apical murmur, but it was usually absent or at least much subdued. Over the pulmonary area a murmur was usually present, but less marked. Here, again, my notes are defective. In one case only so far has the murmur gone with the lessening dilatation. Time hinders me from discussing the medical aspect of the subject; my knowledge, too, is very limited. My opinion, however, is that the changes are due to endarteritis and endocarditis. Many may suggest that the murmurs are purely hæmic. The prognosis so far is unfavourable for complete recovery, but the future may prove this view to be incorrect.

I will now give extracts from my brief and deficient notes:—

CASE 1.—The patient, a young man aged eighteen years, was ill on Feb. 25th, 1895, and became gradually worse. When seen on March 3rd there was pneumonia in the right lung, the left lung being subsequently affected. No note was made as to the heart. On the 8th a murmur replaced the aortic first sound. His pulse kept at 50 per minute. The temperature was normal or subnormal in ten days from the first rigor.

CASE 2.—The patient, a man aged twenty-eight years, was

seen on March 1st, 1895, but not examined because he was dressed. The temperature was subnormal and the skin cold and clammy. About a week later, before allowing him to return to work, I felt his pulse, and it intermitted twice in a minute. The heart was found to be enlarged, and a systolic aortic murmur was present. He had been a vigorous bicyclist, so that the mischief may be old, but I believe it to be of recent origin.

CASE 3.—The patient, a young man aged eighteen years, had been ailing with a cough for three weeks, and had become worse. On March 7th, 1895, there were shivering, vomiting, pains, cough, headache, and vomiting of blood, according to the mother's statement. When seen on the 8th there were pneumonia of the right lung and dullness of the left apex. The heart was enlarged, the sounds being only suspicious. The apex beat was in the nipple line, cardiac dullness extending to the mid-sternum. The pulse-rate was 50. On the 23rd he was recovering from otitis media. The heart dullness was lessening, the apex beat was within the nipple line, an aortic systolic murmur was now present, and the aortic second sound was roughened.

CASE 4.—The patient, a woman aged thirty-four years, had a gradual illness following a cold or influenza three weeks before, aggravated by cold weather and fog. There was increasing weakness, with difficulty in breathing, diarrhoea, and pains over the body just before she was laid up. She had been anæmic before the present attack. She suffered from intense chlorosis, dyspnoea, and a full, throbbing pulse. There was slight dullness of the right apex, front and back. The apex beat of the heart was in the nipple line and accompanied with a well-marked thrill (which was gone in a day or two). The heart was also enlarged to the right. An aortic systolic murmur was present, very loud, and heard all over the chest. The temperature was 100° F., and the pulse 100. For weeks there was a slightly raised temperature. She was rheumatic. The right lung and then the left became congested from the apex downwards. The pulse kept at from 60 to 64. On March 20th, 1895, when last seen, the apex was well within the nipple line; the dilatation, in fact, diminished at once. Murmur was present, but not so loud.

CASE 5.—The patient, a woman aged twenty-two, living two miles away, walked into Folkestone one evening, walked home, and was then taken with something choking her in the throat. She returned to Folkestone with a friend and consulted me early in March of this year. She had symptoms of influenza. I could make out nothing, but suspected angina pectoris. The usual cardiac signs were present. Her temperature was 100° F. She was not seen again.

CASE 6.—The patient, a woman aged twenty-three years, had been ill fourteen days previously with diarrhoea, vomiting, and headache. Her present illness began on March 19th, 1895, with headache, retching, vomiting, and pain in the left side. She was seen on the 20th. The temperature was subnormal. She was very short of breath, and had nervous prostration. The left lung was more or less dull all over the back and the right apex. The heart was dilated (left ventricle), the apex beat being in the nipple line. The action was very tumultuous, and there was a systolic aortic murmur. On the 25th the apex beat was in a normal situation. The murmur had practically gone, the right lung was dull, and the breathing was feeble.

CASE 7.—The patient, a woman aged twenty-seven years, came to me with the heart dilated and an aortic systolic murmur, which is still present (March 26th, 1895).

CASE 8.—The patient, a young woman aged eighteen, came to me complaining of indigestion and pain in the chest since March 24th, 1895. There had been pain in the head a week previously, and also when her sister had influenza at the end of February. She was manifestly anæmic and short of breath. On the 29th the pulse-rate was 76 and the temperature 98.8° F. The impulse of the heart was heaving and forcible. The apex beat was felt mostly just within the nipple line, but also outside. There was a distinct thrill. Dullness extended nearly to the mid-sternum. A systolic murmur at the apex going to the axilla also extended upwards to the aortic area, where it took the place of the first sound. There was a loud, *bruit de diable*. There was pulsation in the neck, arterial and probably venous. The lungs exhibited a slightly impaired resonance and respiration in the right apex (back). On April 1st there was dullness in the right apex and down the lung (back).

CASE 9.—The patient, a woman aged thirty-eight years, was ill at Christmas—from influenza, she believed, and as I do now. When seen at Christmas there was great dyspnoea.

The heart was enlarged; a double aortic murmur was present and remains. There were general bronchitis and broncho-pneumonia of the hypostatic type. The left lung was more or less solid, and very little air entered. The left apex at the back remained dull. Her condition has not changed much.²

Remarks on the nature of the pulmonary complications of this epidemic.—The absence of pleurisy and true pneumonia is remarkable. Whether the heart was affected or not, the signs were much the same. An oedematous or hypostatic congestion seemed to occur in almost all the cases. Bronchial breathing was rarely observed—I suppose because so little air entered the smaller air passages. Taking the number of all those who had lung signs with or without cardiac mischief, mild and severe together, the cases amounted to thirty—i.e., males thirteen, females seventeen. Except in the case of two or three children, and of those who had one or both lungs entirely affected on my first visit, the rule seemed invariable that the mischief should begin at one or other apex (posteriorly), the congestion spreading downwards from above. In many cases, one lung being much affected, a similar process, though of less degree, would start from the other apex. The right apex was the commonest to begin. If the left apex was the first to be affected, almost invariably the right followed suit, whereas, if starting in the right, the trouble generally did not pass to the left. Of the total cases the right lung was affected rather more than the left. Besides the dullness, there was very feeble breathing over the affected lung. Moist sounds generally were absent, except in two or three cases of the acute bronchitic type, which, by the way, were the worst cases, and accounted for the two deaths of the series. If crepitant râles occurred at all, they were very few and appeared late. If taken early and treated heroically, the condition might have passed away within from twenty-four to forty-eight hours, but neglected cases were most tedious and alarming. The cases were generally favourable. There were two deaths—one in a man aged eighty, from hemiplegia, and the other in a woman aged seventy-four, who was dying when first seen. As might be expected, those who suffered severely were the aged, the bronchitic, and the neglected cases, including those who had heart complications. Amongst children I had only three lung cases. The temperature might be sub-normal, normal, or only slightly raised while the mischief was spreading. In conclusion, for those who might suggest that drugs were the cause of this condition I may add that as a rule, with few exceptions, the condition had started, or was well advanced, before treatment commenced, and that my drugs were limited, save in a few instances, to liquor ammoniac acetatis and tincture of squills, both in efficient doses and frequently repeated. The occasional use of salicylate of soda was invaluable. During this epidemic I used very little of the last-mentioned drug, because there was not often any indication for its use, except for "rheumatic" cases; but during the former epidemic I used it largely, with the happiest result, in acute influenza and at the beginning of the true lobar pneumonias which I met with so frequently during its prevalence. With due deference to Dr. Burney Yeo, I must state that I think quinine is not "a specific" for influenza, but that salicylate of soda is such undoubtedly; and that if the drug is used rationally in medium or even small doses, often repeated during the first twelve hours, not only our own but our patients' feelings will be much relieved, and they are often saved from much suffering by the timely suppression of an incipient pneumonia.

Folkestone.

CASE OF DILATATION OF THE COMMON BILE-DUCT SIMULATING DISTENSION OF THE GALL-BLADDER.

By F. H. EDGEWORTH, M.B., B.C. CANTAB., B.Sc. LOND.,
ASSISTANT PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY; LATE
PHYSICIAN TO THE BRISTOL CHILDREN'S HOSPITAL.

IN the course of remarks¹ on a case of Cholecyst-enterostomy Mr. Paul Swain of Plymouth recently referred to an abstract² of a paper I read at the Bristol Medico-Chirurgical Society with the above title in February, 1894. I delayed reading the paper, and subsequently the publication

of any detailed account, in the hope of coming across cases which might throw some light on one which, as far as I knew, was unique. The publication of Mr. Paul Swain's paper induces me to offer it for discussion.

The patient, a little girl, was admitted to the Bristol Children's Hospital in November, 1892, having been sent to me by Mr. Hadwen of Highbridge. The mother said that she and her husband had always been healthy and that they had three children aged respectively six years, four years and a half, and two years and a half, the middle one being the patient. There had been one miscarriage subsequent to the birth of the youngest. She could not remember that any one of the children had suffered from jaundice immediately after birth. The patient was quite well until the age of six months, when whilst still breast-fed she had an attack of jaundice which lasted two or three weeks. Since then she had had slight recurrent attacks every six months or so. Otherwise she had been strong and well, grew as fast as the other children did, and began to walk and talk when about fifteen months old. About a year before admission, however, when three years and a half old, the "child's stomach began to grow big," and this enlargement slowly increased, though none the less the girl appeared to be in good health until about four weeks before, when she became thinner in the body and face. On examination it was found that the patient was well-grown for her age and moderately nourished. There was a slight lemon-yellow tint of the conjunctivæ and skin. The head, heart, and lungs were normal. The urine contained a small amount of bile pigments and no albumen. The motions were bile-stained. The liver was enlarged, the upper limit of dullness on percussion over it extending to the upper border of the fourth rib in the nipple line, and its lower edge in the epigastric notch being lower than normal. The surface of the liver in the latter situation felt smooth and firm. Immediately beneath the abdominal wall, in portions of the epigastric, umbilical, right hypochondriac and lumbar regions, an intra-abdominal tumour was found, measuring about three inches in transverse and three and a half inches in longitudinal diameter, with a lower edge one inch below the level of the umbilicus. The tumour was slightly movable laterally, of a rounded shape and smooth surface, with an elastic feel like a tightly distended bladder. Fluctuation was doubtful. The tumour was dull on percussion, and this dullness was continuous with that of the liver above. The spleen was enlarged, with a lower edge two inches below the costal margin. There was no ascites.

The diagnosis was somewhat doubtful. The tumour was considered to be a distended gall-bladder. The presence of jaundice showed that the obstruction must be in the common bile-duct. As to the nature of the obstruction, aneurysm, malignant growth, and gall-stones could be excluded by the age of the patient and the history, and a tuberculous gland pressing on the duct seemed most improbable. It was concluded that the obstruction was probably due to repeated attacks of catarrh of the bile-ducts. The difficulty was that the slight amount of jaundice indicated that the obstruction was not complete, and yet this did not agree very well with the great distension of the gall-bladder.

As it was obvious that no medicinal treatment could do any good I asked Mr. Ewens to see the patient with a view to operation. A cholecystotomy was performed in two stages; 29 oz. of normal bile were evacuated and a drainage-tube was inserted. The cause of the obstruction was not discovered. In a few days the jaundice disappeared, and the child appeared to be getting on fairly well, when a week after the operation she died suddenly from cardiac failure. The cause of this was not known, nor was it explained by the post-mortem examination on the following day. The brain, thoracic organs, stomach, intestines, and kidneys were normal. The spleen was enlarged. The wall of the supposed gall-bladder was firmly adherent to the abdominal wall round the opening made. There was no general peritonitis. On dissecting the bile passages I found that the sac was not, as had been thought, a distended gall-bladder, but the result of dilatation of the common bile-duct. The gall-bladder was very small and contained a little inspissated bile. The cystic duct was obliterated, a fibrous cord only marking its presence. The lower end of the common bile-duct was stenosed; its lumen admitted a hairpin. The middle portion of the common duct was distended into the (now shrunken) sac, which had a thick wall consisting of layers of fibrous tissue. The common duct

¹ Since writing this article I have seen improvement and even disappearance of the heart signs in several of the cases given above.

² THE LANCET, March 23rd, 1895.

³ Bristol Medico-Chirurgical Journal, June, 1894.

above this and the hepatic duct were somewhat dilated, as were also the biliary ducts. The liver was enlarged and in a state of biliary cirrhosis.

The etiology of the condition found is not very clear; it seems probable that, as was at first supposed, there were repeated attacks of catarrh of the ducts, a catarrh which was not confined to the common duct, but which spread to the cystic duct, resulting in the former situation in stenosis and in the latter in total obliteration of its lumen. The enlargement of the spleen was to be expected, for it is a constant feature in biliary cirrhosis and occurs in those cases of alcoholic cirrhosis in which there is jaundice. Possibly, however, this is not a complete solution of the case. Dr. John Thomson of Edinburgh has in a valuable paper² collected all the cases and discussed the etiology of the condition known as "congenital obliteration of the bile-ducts," a disease the characteristic features of which are a permanent jaundice which is apparent at birth or appears a few days afterwards, and a liability to hæmorrhages from the skin, umbilicus, and gastro-intestinal tract. The child lives but a short time, though in some cases as long as several months, but sooner or later dies either from convulsions or gradual failure. The condition found after death is an obliteration of one or other portion of the common or hepatic duct. Dr. Thomson comes to the conclusion that there is some congenital affection of the duct, probably a stenosis, and that at a variable period in intra-uterine life a consecutive and consequent catarrh leads to total blocking and obliteration. This suggests that in the case here described there might have been a stenosis, which, though not sufficient to cause a permanent jaundice at birth, yet favoured the development of repeated attacks of catarrh a little later in life. In favour of this may be mentioned that it is unusual to find repeated attacks of catarrhal jaundice in a patient at the early age—six months—at which the first attack came on. Children do not as a rule become liable to catarrhal jaundice until they begin to take solid food. It seems possible, then, that there is a class of cases in which the fundamental defect is a slight stenosis of the bile-ducts. Such cases are characterised by the occurrence of repeated attacks of jaundice in early life. The liver in the course of time passes into a state of biliary cirrhosis. If the stenosis be most marked in the hepatic duct these will be the main phenomena; if it be lower down the common bile-duct may become distended into a retention cyst. It may, perhaps, be suggested that some cases of unexplained cirrhosis of the liver may be in reality due to this cause. The following may be an instance. A girl two years of age was brought as an out-patient to the Bristol Royal Infirmary on Jan. 14th, 1894. Her mother said that she had three other children, all older than the patient, and that she had had no miscarriages. The patient had icterus neonatorum lasting a month. She had jaundice when a year old lasting two weeks, and the present attack had begun two weeks before admission. Her mother said the child had never had any alcohol, and had not suffered from any specific fever or from any other illnesses. On examination it was seen that the skin and conjunctivæ were of a lemon-yellow colour. The liver was enlarged, reaching half an inch below the costal margin, its surface felt rather firm, and its edge was corrugated. It was five weeks before the jaundice disappeared, and at the end of that time the liver was in the same state as when the child was first seen.

If dilatation of the common bile-duct occurs it will not be possible to differentiate it from a distended gall-bladder until operation, when it will be seen that the supposed gall-bladder has no mesentery attaching it to the under surface of the liver. It is somewhat doubtful whether Mr. Paul Swain's case can be placed in this category, for the patient had no jaundice until the age of sixteen years. The case above related certainly shows, however, that a block in the common duct may lead to distension of the duct above into a large sac, and supports his suggestion that the case he operated on may have been such a one. One point further may perhaps be noted—viz., that so little jaundice was produced by a stenosis sufficient to produce so great a distension of the common bile-duct. Possibly a partial explanation may be found in two facts: the bile secreted is largely merely a re-excretion; and blood destruction—the primary source of bile pigments—is much slighter in children than in adults. Similarly in cases of catarrhal jaundice in children, even when the obstruction as shown by the motions is complete, the jaundice is rarely more than slight.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A COMPLICATED MIDWIFERY PRESENTATION.

By R. HILL SHAW, B.A., M.B., B.Ch. UNIV. DUBL.

I WAS recently called to a case of midwifery and found on vaginal examination a hand, a foot, the funis, and the vertex presenting. The hand, which I made out to be the right, and which seemed to be larger than normal, was situated to the right of the symphysis pubis. Behind and at the upper part of the right side of the hollow of the sacrum was the foot, though on a higher level than the hand. Entwined around these was the funis, which had no pulsations, and a little further up than the foot, in the left occipito-anterior position, was the vertex, partially engaged in the pelvis. The possibility of twin pregnancy presented itself, but of this, however, I could not find any confirmation. This was the woman's fourth confinement, all her previous ones having taken place wit out any hitch. Her age was twenty-six years. I could not get any exact history of how long the membranes had been ruptured. The pelvis was roomy. The pains were so strong and frequent that I could not get an opportunity of passing my hand past the presenting vertex. Failing this, and as labour was not progressing, I tried by pushing up the leg and the arm with the funis to engage the head in the brim, but without success. Traction on the foot and version were tried with similar want of success, owing to the whole presentation being tightly jammed into the opening of the pelvis. These attempts occupied about an hour. I then went for my principal, Mr. Anderton, and in a very short time returned with him, when we found that labour had made rapid progress, notwithstanding that the presentation was still as described above. The hand by this time was outside the vulva, and the head was well engaged in the pelvis. The forceps was applied and delivery was completed in a couple of minutes. The child, which was dead, lay in the following position: the right arm was extended at full length above the head, and the right leg was flexed up along the body, reaching over the right shoulder; entangled around these was the funis. The child was of full time and fully developed, and the mother stated that she had felt it move a couple of hours previously to sending for me. The largeness of the hand was due to oedema, the result, no doubt, of pressure, which also acting on the cord produced asphyxia. New Mills, Derbyshire.

A CASE OF EXTRA-UTERINE FETATION OF THREE YEARS' STANDING.

By ANNA LYDIA CHURCH, M.B. R.U. IREL.

A HINDU woman aged twenty-five years, married, was admitted into the Free Church of Scotland Mission Hospital, Madras, on Nov. 1st, 1894, in an evidently wretched state of health. On examination the abdominal wall, a little below and to the right of the umbilicus, was found to be destroyed by ulceration, leaving a space of four or five inches long and about three broad, through which protruded an evil-looking, exceedingly offensive tumour. A strap of integument crossed the centre of the space and covered a small portion of the tumour. At first sight the mass suggested an intra-abdominal malignant growth that was undergoing necrosis and had ulcerated through the abdominal wall. Closer inspection, however, revealed a white, hard plate with serrated edges projecting from the surface. This proved to be bone, and when the end of a tiny long bone was afterwards found the diagnosis of extra-uterine foetation was clear. The first bone belonged to the cranium. The history elicited from the patient and her friends was somewhat meagre and was as follows. Three years previously she consulted a medical man and was told that she was pregnant. Two years elapsed, but no child was born. Amenorrhœa prevailed during this period. A lump was noticed in the abdomen and eleven months before admission the skin over it began to give way and pus escaped, but it was not till

about eleven days before admission that fetor was noticed. The patient's condition on entering the hospital was deplorable. She was so feeble that she had to be carried upstairs to the ward; her pulse was small and rapid, and her temperature 101° F. An attempt was made to cleanse the mass and diminish the fetor by repeated antiseptic washings and dressings until arrangements could be made for operation, during which treatment numerous live maggots made their appearance from the crevices of the tumour and were removed. A day or two after admission the patient was put under chloroform and the foetal remains removed. I had arranged to cut the strap of integument with Paquelin's thermo cauterium so as to avoid producing bleeding surfaces, which might favour septic absorption; but on removing the dressing it was found that the strap had given way and that no cutting was necessary to enlarge the opening, and the only instrument used during the operation was a pair of dissecting forceps. First there came away a shapeless mass containing the ribs and some other bones of the foetus, and then the remainder of the bones were removed piecemeal, some of which were lying loose and others partially embedded in the walls of the sac. The extraction of these last caused slight bleeding at one or two points. From a tunnel in the wall of the sac several live maggots emerged. The fetor was sickening. The bones appeared to belong to a foetus of about four months old. The sac was thoroughly flushed with boiled water and was then filled to the brim with sublimate solution (1 in 1000), which was allowed to remain for several minutes and then poured off. It was lined with a layer of foul necrotic tissue, but I refrained from scraping it, fearing that the production of a large raw surface might be the cause of fatal sepsis, and judging that with careful use of antiseptics the necrotic tissue would come away harmlessly on the dressings. The sac was accordingly filled with iodoform gauze soaked in iodoform and glycerine, and carbolic tow placed over it.

The result of the operation was most gratifying. The temperature fell to normal at once, and the horrible fetor which had rendered the patient's life miserable disappeared. The pulse-rate fell gradually. The sac was washed out and dressed twice daily, ichthyol and glycerine being substituted for the iodoform emulsion, as the stock of iodoform happened to run short at the time. The walls were merely painted with the ichthyol. The sac rapidly cleaned and contracted, and began to fill up from the bottom. Small fragments of bone were found on several occasions on "sounding" the walls with the point of the forceps and were removed. The patient was given a fair amount of brandy at first and abundant nourishment, and was able to be up about a fortnight after the operation. She was discharged on Dec. 1st and attended as an out-patient till the wound completely closed. One small granulating surface refused to heal for some time, and on probing it bone was felt. A fine-pointed pair of forceps was introduced and five small fragments of bone extracted. On a subsequent occasion two more fragments were removed. The wound then promptly closed. Bimanual examination made lately shows the uterus to be high up near the abdominal wall, somewhat retroverted and fairly movable, although numerous adhesions can be felt. There is much ill-defined thickening to the right of the uterus. The patient has had two normal periods since leaving hospital.

Madras.

PRESENTATIONS.—Dr. Francis R. Russell of Guildford has been presented by the Surrey County and Guildford Borough Police Force, in connexion with the St. John Ambulance class, with a riding watch bearing the following inscription:—"Presented to Dr. F. R. Russell by the Surrey County and Guildford Borough Police Force as a slight recognition of his valuable and honorary tuition throughout a course of lectures of first aid to the injured to the St. John Ambulance Association. April, 1895."—Dr. A. W. Anderson, Dalbeattie, Kirkcudbrightshire, was presented with a valuable travelling bag and dressing case on the completion of his course of ambulance lectures by the members of his class in connexion with the St. Andrews Ambulance Association.—Mr. G. N. Coombes, late assistant to Dr. L. Williams, on his leaving Wrexham to take up an appointment in India as surgeon to his Highness the Rajah of Cochin, was presented by his friends with a handsome smoker's cabinet, which bore a suitable inscription upon it, and he was also entertained to dinner by his colleagues of the medical profession.

WESTMINSTER HOSPITAL.

NOTES OF THREE CASES OF HERNIA OF AN EXCEPTIONAL NATURE.

(Under the care of Mr. W. G. SPENCER.)

THESE cases, although the treatment was unsuccessful in saving life, are of interest from a clinical standpoint and are fully commented on by Mr. de Santl in his remarks. Opinions must always differ as to the treatment of gangrenous intestine when it is met with while operating for hernia; the condition of the patient is usually bad from every point of view, and as we may take it for granted that those which have been submitted to resection are the most favourable cases it is hardly possible to compare on equal terms statistics of the two methods. Each surgeon must judge for himself and not trust to strict rules to guide him. For the account of these cases we are indebted to Mr. Philip R. W. de Santl, surgical registrar, from notes by Messrs. Penny, Ambrose, and A. J. Smith.

CASE 1. *Strangulated femoral hernia (Littre's), the sac containing a gangrenous diverticulum; spread of gangrene to gut internal to stricture; peritonitis; resection of gangrenous gut.*—A woman aged seventy-seven years was admitted on Dec. 4th, 1894, with a strangulated femoral hernia. The patient had had a reducible right femoral hernia for eleven years; she had never worn a truss and had never suffered any inconvenience from the rupture. On Dec. 2nd between 1 and 2 P.M. the hernia came down suddenly (no exertion), and was of a larger size than on previous occasions. She had acute local pain, which soon extended to the whole of the abdomen. Retching, but no vomiting, commenced a few hours later; she passed flatus by the mouth, but not by the rectum. The bowels had been open each day before, but had now become constipated. On admission an ovoid swelling hard in parts, soft in others, and emphysematous was found in the right femoral region external to the spine of the pubes. The skin over it was red and inflamed but movable. There was no impulse on coughing. There had been constant nausea but no vomiting, and absolute constipation since Dec. 2nd. The patient was very collapsed and was suffering from bronchitis and emphysema. The pulse was 120 and the temperature normal. Mr. Spencer decided to operate at once. Nitrous oxide gas and then ether were administered and the ordinary incision made over the tumour. A mass of gangrenous subperitoneal tissue was exposed and removed. The hernial sac was then seen and opened, and found to contain a piece of gut of the size of a walnut, very tense, ashy black, and covered with beads of gas. As much as possible of the sac was cut away and the exposed gut incised. A quantity of sanious fluid escaped, and the bowel was then snipped off flush with the femoral canal; in the centre of the remaining part a depression was felt, but no force was used to pass the finger into the femoral canal. The wound was then swabbed out with glacial carbolio acid, a drainage-tube inserted, and the wound closed with deep silk sutures. The patient stood the operation well. She slept well till about 4 A.M. on Dec. 5th, when she began to vomit coffee-coloured faecal matter, about one pint in quantity; she also complained of severe abdominal pain. The pulse was 96, regular. The temperature was normal. At 8 A.M. the vomiting ceased. An enema was given on the night of Dec. 5th, but with no result. Vomiting started again at 2.35 A.M. on Dec. 6th and lasted till 9 A.M. The patient was weaker, but did not complain of pain. She had yzimid suppositories, one every three hours. As the vomited material was faecal a second operation was decided on by Mr. Spencer, who was assisted by Mr. de Santl. The original incision was continued upwards for about two inches through the abdominal walls and Poupart's ligament divided. No gut was found in the femoral canal, but a piece of small intestine

gangrenous for about two inches of its length was found just above Poupart's ligament and was connected with a diverticulum the stump of which was in the femoral canal. The gangrene had thus extended for two inches on either side of the diverticulum well inside of any constriction. The gangrenous gut was torn a little as it was lifted and there was extravasation of faecal material which was caught on a sponge. The gangrenous piece of intestine was excised and the two healthy ends united by a Murphy's button and the wound irrigated with a 1 in 40 carbolic lotion and closed. The patient gradually sank and died at midnight on Dec. 6th.

Necropsy.—The soft tissues about the wound were in a condition of diffuse suppuration. On opening the abdominal cavity the peritoneum was found to be of a dark-red hue and covered with yellow lymph, which was thickest and most abundant in the right iliac region and in the pelvis. In these regions several coils of intestine were matted together and to the internal aspect of the wound. Among them was found the resection wound, and inside this portion of gut (eight feet from the end of the duodenum) a Murphy's button. Immediately around the resection wound the gut was of a darker colour than elsewhere. After cutting out this portion water was found to percolate slowly between the stitches on the free aspect of the gut. The rest of the gastro-intestinal tract and the other organs were normal.

CASE 2. Intestinal obstruction; kinking (?) of gut in region of caecum from a subperitoneal lipoma: subsequent gangrene of the greater part of the small intestine in a pregnant woman the subject of tertiary syphilis and nephritis.—The patient, aged thirty-eight years, was admitted into the Queen Anne Ward on Feb. 6th, 1895, with symptoms of strangulated femoral hernia. The patient had had a right reducible femoral hernia for twelve years and had worn a truss for the last eight years. Four months ago, having taken off her truss prior to going to bed, the hernia suddenly came down; at the time she was lifting one of her children into a chair. A medical man tried taxis, but unsuccessfully. There was acute pain in the right groin and abdomen, but no vomiting. During the early morning the hernia went back of itself. On Feb. 4th, 1895, at 3 P.M. the patient was stooping down in the act of dressing her child when the hernia again descended suddenly though she was wearing her truss at the time. A medical man tried taxis, but ineffectually; vomiting soon set in, the matter vomited being a greenish, very offensive liquid. The sickness continued during the night of Feb. 4th and also constantly on Feb. 5th and 6th. The bowels were open freely on Feb. 5th. On admission the patient was collapsed, with a temperature of 96.4° F. The house surgeon distinctly felt the hernia, but did not attempt taxis, as it had been repeatedly tried outside. He gave the woman twenty minims of tincture of opium and ordered a hot bath, and sent for the surgeon of the week. The patient shortly after admission vomited three times; the vomited matter was green and very offensive. When seen by Mr. Macnamara no hernia was discoverable. The bowels acted three times, the motions being loose. On Feb. 7th the temperature was 96.4°. The pulse was small and feeble. The tongue was dry and brown. She slept badly, vomiting about every hour. The bowels were open six times. At 9 P.M. the patient was examined by Mr. Spencer, who found a movable, soft swelling in Scarpa's triangle about one inch in diameter and rather external to the saphenous opening. Under either the right femoral canal was explored; no hernia or hernial sac was discoverable. The soft swelling proved to be a mass of subperitoneal fat the pedicle of which was followed into the right inguinal canal and found to be closely connected with the round ligament. It was separated, ligatured, and cut off within the abdominal ring. The femoral and obturator rings were then examined from within the abdominal wall, but outside the peritoneum; they were quite free. On Feb. 8th there was marked general improvement. The patient had not vomited since the operation and was being fed on nutrient enemata. On Feb. 9th improvement was still maintained. She was fed by the mouth with milk, beef-tea, and brandy. The bowels were freely open after enema (Feb. 8th). On Feb. 11th she complained of abdominal pain; the abdomen was not distended. The bowels had not been open since Feb. 8th. The temperature was subnormal. On Feb. 12th she vomited for the first time since the operation. The vomited material consisted of beef-tea and milk. She had great abdominal pain, but no signs of peritonitis. The bowels were open on Feb. 11th and 12th after an enema. The wound healed by first intention. On Feb. 13th the patient had a restless night and died at 11 A.M. from assthenia.

Necropsy (twenty-eight hours after death).—The body was much emaciated. In the peritoneal sac were five or six ounces of dark reddish-brown clear fluid; the peritoneum everywhere was smooth and shiny; the mesentery was not thickened; the intestines were not distended; the small intestine, with the exception of the first and last two feet, was of a dark-purple colour, was somewhat swollen, and as far as the central moiety was concerned was in a condition of gangrene. There was, however, no obvious swelling of the veins and arteries, certainly none in the mesenteric vessels. The surface of the gut had a slightly worm-eaten appearance, but there was no definite ulceration. The small intestine contained a thickish bloody fluid. There were no constriction marks. The lymphatic glands were not enlarged. The large intestine, except the caecum coli, which was hyperæmic, contained semi-fluid yellow faeces and was quite normal. The stomach, liver, spleen, and pancreas were normal; as to the kidneys the capsule was thick and adherent, the surface granular, the cortex diminished and of flabby consistence, and the colour drab. The bladder was contracted. The heart weighed 8 oz.; there was slight hypertrophy in the left ventricle. The valves were competent, the mitral flaps being thick. The foramen ovale was patent, but valved. The arteries and lungs were normal. The uterus was 4½ in. long and 3 in. across the fundus. It contained a foetus of about two and a half months. There was a corpus luteum in the left ovary.

CASE 3. Strangulated inguinal hernia; reduction "en masse"; abdominal section; intestinal paralysis; death.—A man aged fifty-one years was admitted on March 5th, 1895, suffering from symptoms of strangulated hernia. The patient had had a right reducible inguinal hernia for thirty years. His medical man, Mr. Munyard, has kindly supplied the following notes. The patient had a fall seven weeks previously, and was left on the pavement for some little time. He apparently got a chill, and had a cough with raised temperature for a week, and influenza was diagnosed. On Sunday, March 3rd, the patient was very sick, and the effort of vomiting, according to the patient's statement, brought the hernia down. The man tried to reduce it, but failed, though he had always succeeded before; later in the evening he, however, apparently returned it. On March 4th Mr. Munyard was visiting a patient who lived in the same house as the one in question, and his attention was called for the first time to the rupture. The man was then suffering from stercoraceous vomiting, and there was a distinct inguinal hernia of the size of two walnuts. Mr. Munyard easily reduced it, but noticed that the hernia did not go back with a slip or gurgle, but as a whole. On March 5th on again visiting the patient he found that severe vomiting had continued all night, that the vomited matter was faecal, and that the patient was very collapsed. The inguinal canal was quite free, but did not feel preternaturally open. The bowels had not acted since March 2nd. He was sent at once to the Westminster Hospital and admitted. A diagnosis of reduction *en masse* was made and median laparotomy was performed by Mr. Spencer. On opening the peritoneal cavity a well-marked reduction *en masse* was seen, the hernial sac and its contents having been pushed back into the abdomen and the peritoneum doubled up before it. The gut was tightly nipped at the neck of the sac; about six inches of the gut were considerably congested and of a dark colour, and at the actual site of constriction the gut was ulcerated for about three-quarters of an inch of its circumference. The neck of the sac was divided and left *in situ*. The ulcerated part of the gut was closed with Lembert's sutures and then left in a furrow so that adhesions might form around it. The pillars of the canal were then sutured together from the outside and the abdominal wound closed in the usual way. The patient progressed very favourably up to March 9th, the vomiting having ceased and the bowels acting of their own accord daily. On the 9th, however, the abdomen became distended and there was much pain. On the 10th the patient died, the abdomen having gradually become more distended and the patient weaker. A post-mortem examination was refused.

Remarks by Mr. DE SANTI.—Case 1.: The prognosis in this case was particularly unfavourable; the patient's advanced age—namely, seventy-seven—the duration of the symptoms of strangulation (over forty-eight hours), and the gangrenous condition of the contents of the sac together presented such a formidable condition of affairs that recovery could hardly be expected; added to which, owing to the continuance of the symptoms of strangulation after the herniotomy, it was deemed advisable to undertake a second operation, whereby a piece of gut, gangrenous for about two

inches of its length, and lying just above Poupart's ligament, was discovered. The question then arose as to whether, in the patient's collapsed and desperate condition, it would be judicious to perform immediate resection and suture of the gut or establish an artificial anus. As it was recognised that the gut that was gangrenous was high up, probably the upper part of the jejunum, Mr. Spencer considered that the establishment of an artificial anus was out of the question. Resection of the gut and union of the healthy ends by means of a Murphy's button were therefore decided on and performed, as holding out the only chance of recovery and as being the most rapid method practicable. It is not my intention in these short remarks to go fully into the treatment of gangrene of the intestine due to strangulation in hernia, a subject upon which there is a considerable diversity of opinion. It will suffice for me to say that gangrenous hernia may be treated on one of two principles: either (1) by resection of the affected portion and immediate suture, or (2) by the formation of an artificial anus. According to Macready,¹ the rule of treatment among surgeons in London at the present day is to form an artificial anus, and he states that of twenty-one London surgeons who have expressed their views upon this subject in public of late years seventeen are in favour of forming an artificial anus and four of doing primary suture. I personally, though my experience is necessarily small, am in favour of establishing an artificial anus in the great majority of cases, for it seems to me that primary suture has to be carried out under the most unfavourable circumstances, the tissues being in a most septic state, the exact limits of the gangrene uncertain, and the risks of subsequent extravasation, sloughing, or giving way of some of the sutures great. The operation also is a difficult one to perform, and though its difficulty is no objection it takes from one to four hours (M'Cosh) to carry out, and as the patient is usually in a state of considerable collapse his condition is hardly such as to stand the additional shock caused by so long and severe an operation as resection and suture. Of those, however, who advocate resection and primary suture I may mention Mikulicz, Lockwood, and Kendal Franks. Mikulicz collected recently (1891) 173 cases of gangrenous hernia, of which 94 had been treated by the formation of an artificial anus and 67 by primary suture; the mortality in the former was 76 per cent. and among the latter 47 per cent. Lockwood collected 35 cases from the clinical records of St. Bartholomew's Hospital, all of which had been treated by the formation of an artificial anus, with a death-rate of 88.5 per cent. He compared these with the mortality of cases treated by primary suture from tables of Makins and M'Cosh, and obtained a difference so greatly in favour of primary suture that he strongly advocates its general employment in gangrenous hernia. Again, Kendal Franks of Dublin² collected from various sources 202 cases of gangrenous hernia treated by the formation of an artificial anus and giving a mortality of 80.7 per cent., and 222 cases treated by primary suture and giving a mortality of 47 per cent. He is strongly against the establishment of an artificial anus as the routine practice. Notwithstanding, however, these favourable statistics I would be inclined to perform resection and immediate suture under the following conditions only: (1) in young patients, and where the state of the patient is such that he will be able to stand the prolonged anaesthesia required by the operation—in other words, where there is no profound collapse; (2) in the absence of a generalised peritonitis; (3) in the absence of great distension of the afferent piece of intestine, which is often filled with quantities of faeces and gases; (4) when it is possible to draw out the whole of the gangrenous portions of the intestine and mesentery, and resect in healthy tissue; (5) when there is no great difference between the calibre of the two ends, and they can therefore be thoroughly and efficaciously united; and (6) in the presence of good assistants and the necessary surgical appliances for anastomosis or suture. The presence of a distinct diverticulum about an inch and a half in length in the hernial sac is a point of some interest in this case; whether it was a true congenital diverticulum of the intestine, consisting of all the coats of the gut, or a false variety (pouched partial enterocoele) formed by the protrusion of the mucous membrane between the fibres of the muscular coat and projecting from the bowel, is a point of some doubt owing to the condition of gangrene in which the tissues and diverticulum were found. In Mr. Spencer's opinion the diverticulum was of congenital origin.

Case 2 presents many features of great interest. For twelve years the patient had apparently had a swelling in the region of the right femoral canal and had worn a femoral truss to keep it up; four months before admission, the truss being temporarily off, the swelling appeared, causing great pain but no vomiting, and went back, according to the women's statement, of itself. Two days before her admission to Westminster Hospital a similar condition of affairs occurred, and the patient on admission had a swelling in the femoral region which was distinctly felt by the house surgeon, but which had apparently disappeared when Mr. Macnamara examined the patient a little later. Between Feb. 4th and Feb. 7th the patient suffered from pretty constant vomiting, but her bowels acted freely and there was no pain in or swelling of the abdomen. On Feb. 7th Mr. Spencer on examining the woman found a soft, movable mass in the neighbourhood of the femoral canal, and as vomiting persisted he explored the femoral canal but found no trace of sac or hernia, but a sub-peritoneal lipoma running up into the right inguinal canal; this was ligatured and removed, and the operation considerably benefited the patient, the vomiting having ceased. For a few days she seemed to be going to recover, when gradually a change for the worse was noticed and the patient died from asthenia on Feb. 13th, nine days after the first symptoms. The necropsy revealed a very curious condition of the intestine—namely, intense congestion of the whole of the small intestine, the central moiety being in a state of actual gangrene; there were no constriction marks discoverable and the mesentery and mesenteric vessels were quite healthy. The peritoneum also was quite normal. I am at a loss to account for the condition of the small intestines. The symptoms of strangulation were due possibly: (1) to the subperitoneal lipoma drawing on the peritoneum and kinking the intestines in the region of the ileocaecal valve; and (2) incomplete reduction, completed whilst the patient was going under an anaesthetic, death taking place from failure of peristalsis in a pregnant woman who had suffered from syphilis and chronic nephritis.

Case 3.—In this patient, who had had a right inguinal hernia for some thirty years, which he had been in the habit of reducing with ease himself, symptoms of strangulation suddenly came on, followed apparently by the appearance of the hernia (patient's statement only). At first the man was unable to reduce the hernia, but later appears to have done so. The following day he was seen by his medical attendant, who found a distinct inguinal hernia which he was able to easily reduce, but he particularly noticed that it went back without any gurgle or slip, and that the inguinal canal was particularly free. He diagnosed reduction *en masse*, and from the wrinkled condition of the peritoneum found at the operation, permitting of the easy withdrawal of the peritoneum from the laparotomy wound, it is probable that for some long time past the man had been in the habit of reducing his hernia *en masse*, and that when it became strangulated he returned it *en masse* and in a condition of strangulation. The right inguinal canal and other hernial sites being quite free, there being no tumour or impulse to be felt in the right inguinal canal on coughing and no fulness on palpation over Poupart's ligament, and bearing in mind the fact that in reduction *en masse* the neck of the sac may leave the internal abdominal ring and rise in the abdominal cavity for from one to four inches, Mr. Spencer decided to perform median laparotomy in preference to exploration of the inguinal canal by the usual incision.

PATHOLOGICAL SOCIETY OF LONDON.

Microscopic Structure of Oxalate of Lime Calculi.—Results following the Experimental Removal of Portions of the Kidney.—Elongation of Radius from Osteitis Deformans.

AN ordinary meeting of this society was held on May 7th, Dr. PAVY, the President, being in the chair.

Dr. ORD and Mr. SHATTOCK made a communication on the Microscopic Structure of Calculi of Oxalate of Lime. They began this communication by noticing first the chief microscopic forms of such calculi, the smooth, tuberculated, spiny, and crystalline. The chief forms in which oxalate of lime was met with in the urine were then referred to: octahedron, flattened octahedron, "maclé," in which the bases of the two

¹ Treatise on Ruptures, p. 397.
² Transactions of the Royal Medical and Chirurgical Society, vol. lxxv., p. 215.

pyramids of an octahedron were rotated so that the angles of one projected across the sides of the base of the other, the spherular form, including dumb bells, and the tabular form. The key to the interpretation of these varieties was supplied by the experiments of Mr. George Rainey, made more than thirty years ago, which showed that crystalline substance if deposited in colloidal or viscous media underwent modifications in form which in the most pronounced degree took the figure of perfect spheres. Dr. Ord subsequently studied the question in oxalate of lime &c., causing the salts to deposit in the substance of gelatine by allowing double decomposition to occur in solutions on either side of a diaphragm of the colloid; the solutions met in the jelly, and on cutting sections of this all forms were traceable, from typical crystals to perfect spheres. Some such spheres were compound in structure. The colloid that exercised most influence was albumen. Sugar appeared to have no influence on oxalate of lime, though it had on uric acid. They next proceeded by means of a lantern demonstration to exhibit the microscopic structure of the different forms of calculi. The specimens were prepared by grinding the calculus half through, cementing by means of melted Canada balsam to a slide, and then grinding it from the opposite aspect; this transparent section was then covered, after placing balsam solution on it to render it transparent. The summary as to the construction of the nucleus of such calculi was as follows:—It might be (1) large transparent crystals of oxalate of lime; (2) similar crystals rendered more or less opaque by secondary cleavage; (3) minute crystals not of octahedral form; (4) rosettes of striated conoidal or fan-shaped elements, like those which form by their regular juxtaposition the body of the calculus; (5) spherules in process of coalescence. Such forms might occur in various combinations. In rare cases large octahedra were met with in the urine as "gravel," and by a chance aggregation of such the nucleus usually arose. Very soon, however, the deposit took a different form and constructed the "body" of the stone; this change might be explained by the presence of such a nucleus leading to the admixture of colloid with the urine by reason of the inflammation in the urinary passages which it excited, and this would be mucus or exudation from the vessels of the inflamed mucosa. The secondary cleavage of the large elements of the crystalline nucleus probably indicated the action of colloid in a slight degree. In regard to No. 3, the small crystals were really tablets, and could be produced in gelatine, as could also rosettes of such. The presence of proper spherules was rare. Next, as to the body of the calculus. In all cases the body arose in cones of crystalline substances, sharply pointed at their inner ends and diverging from the outer surface of the nucleus. In transverse section these cones had a very irregular outline, deeply sinuous or jagged, so as to be sutured to one another; they were doubly striated—i.e., in the longitudinal and transverse directions, or radially and concentrically as to the centre of the entire calculus. Both forms of striation might be represented in the spheres artificially produced, but Dr. Ord and Mr. Shattock could offer no real explanation of them. Often there occurred in the body of the calculus zones of a different kind. These were formed by a non-crystalline molecular basis in which lay, concentrically arranged, lines of distinct granules; the latter they held to be urate, the former oxalate, of lime; there was, in fact, no sharp line of distinction between this form of oxalate and the striated. One of the most interesting of the results was the likeness that subsisted between the calculi, as a whole, and the microscopic spheres and crystalline aggregations which might be artificially produced; there were parallel forms in both. In regard to the colouration of oxalate calculi, certain of the sections displayed brilliant crystals of hæmatoidin. That the diffuse colouration was due to urinary pigment they thought disproved by the similar colouration of intestinal calculi of oxalate of lime in herbivora. They thought it most probably due to hæmoglobin. Some of the calculi gave abundant evidence of iron on analysis, probably indicating blood, though as normal urine contained small quantities of iron in as yet an unknown state of combination this did not exhaust the question. Ebsstein had figured a small portion of the body of a calculus of oxalate of lime, but beyond that the minute structure by means of sections had not been investigated. Vandyke Carter's method had been simply to pick out minute pieces from different parts of calculi to examine them.—The

PRESIDENT remarked that some persons would for years pass urinary sand and have no trouble from calculus, while in others who suffered from urinary calculus there was an absence of history of gravel. In many patients again there was a history of one-sided pain, and it appeared in them that one kidney only was at fault. Hence, in these patients there seemed to be a general tendency to the deposition of solid matters from the urine, and a local tendency leading to deposit from one kidney only.

Dr. J. R. BRADFORD then gave an account of the results following the Experimental Removal of Portions of the Kidney. The object of these experiments was to investigate the changes in the urine and in the general nutrition that occurred when an animal had but a fraction of one kidney available for the discharge of the renal functions. The experiments were carried out on dogs, the ingesta and excreta being determined before and after the operation. The nitrogen was determined by Kjeldtal's method. A wedge-shaped portion was excised from the middle zone of one kidney and the cut surfaces approximated by sutures. After an interval of some weeks the entire opposite kidney was excised. The results may be summarised as follows. Removal of a portion of one kidney is followed by a variable amount of general atrophy of that kidney and by hypertrophy of the opposite kidney provided the operation be performed in adult animals. Removal of a portion of one kidney only is followed by a slight increase in the amount of urine excreted, this increase is sometimes only temporary, and there are no other ill effects. If after having excised a portion of one kidney the entire kidney of the opposite side be removed, the following results are seen. If only some two-thirds of the total kidney weight has been removed altogether at the two operations, the animal remains in fair health and does not emaciate. The quantity of urine excreted, however, is greatly increased—i.e., doubled or trebled in amount. There is no increased excretion of urea. On the other hand, if as much as three-quarters of the total kidney weight has been removed then there is a still greater increase in the amount of urine excreted and in addition there is a considerable increase in the daily urea excretion, the animal emaciates rapidly and dies within a few weeks of the second operation. Excision of a wedge from each kidney is followed by the excretion of a large amount of urine, but there is no increased excretion of urea and the animal remains in good health. Hence when the renal tissue is reduced to but one-fourth of its original weight there is not only no diminution in the amount of urine and urea excreted, but, on the contrary, a great increase, the increase in them being dependent upon rapid emaciation, which is not checked by a liberal diet.—Dr. HERRINGHAM said that the experiments which had been related had a bearing on hydruria in renal disease. He asked if increased blood pressure or cardiac hypertrophy had been produced. The other phenomena which had been described were so different from what was seen in chronic nephritis that they could hardly be connected with that affection.—Mr. STANLEY BOYD asked how the hæmorrhage from the kidney had been checked when the wedge-shaped pieces were removed.—Dr. SHERINGTON asked what was the alteration in ratio of the nitrogenous extractives to the urea, and if there was found any body other than urea disproportionately increased either in the tissues or in the urine itself. He asked if the total nitrogen in the tissues had been estimated.—Dr. WASHBOURNE asked if the toxic property of the blood of the animals operated on had been tested.—Dr. BRADFORD, in reply, said that he had detected no cardiac hypertrophy. The blood pressure remained high and abnormally so; but it was very difficult to estimate in a dog under chloroform. In dogs in whom three-fourths of the renal substance had been removed, and who were too weak to stand, the blood was found to contain twenty to thirty times the normal amount of urea, while the blood pressure remained normal. In those dogs in whom double nephrectomy had been performed the blood also contained thirty times the normal amount of urea, but in these there was practically no blood pressure. Patients with extremely granular kidneys might pass a very large quantity of urea. In removing the wedges from the kidney blood was found to come from three sources—viz., vessels in the loose connective tissue of the hilum, general oozing from the cut surface, and bleeding (principally venous) at the junction of the medulla with the cortex. He ligatured the vessels in the hilum and, if necessary, passed a suture under those at the junction of the cortex with the medulla, and controlled the oozing by pressure with cotton wool. He did not close the wound until bleeding ceased. Both the

urea and the nitrogen had been estimated in the food, urine, and faeces. In the urine no nitrogenous body, except urea, had been found, and the same was true of the blood; but in the muscles, liver, and brain, especially the former, a large amount of nitrogenous substance was found which was not urea. He had not yet determined the toxic properties of the blood.

Mr. SHATTOCK showed for Mr. Clutton the bones of an arm from a case of Osteitis Deformans. The radius was markedly elongated, being twisted into an S-shaped curve because the ulna was unaffected. The specimen was very interesting because it showed that interstitial production of tissue in a bone itself as a result of inflammation could actually lengthen the bone after the epiphyses had united and the bone had ceased to grow.

OBSTETRICAL SOCIETY OF LONDON.

The Common Form of "White Leg" occurring after Child-birth.—Exhibition of Specimen.

A MEETING of this society was held on May 1st, Dr. F. H. CHAMPNEYS, President, being in the chair.

Dr. C. HUBERT ROBERTS read a paper giving details of sixteen cases of so-called "White Leg," most commonly met with after child-birth. Having rapidly reviewed the literature of the subject up to the present date, he pointed out the difference of his cases from those described in most text-books of the present day, and argued briefly that white leg described in such books is not the common variety met with after delivery. He described concisely the form he believes to be the common one, mentioning its symptoms, duration, complications, and treatment. He said that the term "white leg" includes several morbid conditions which differ in many particulars, and proposed the following classification of the disease: (1) cases which are due to pressure; (2) cases associated with general disease; (3) cases of a true septic nature; (4) cases of thrombosis apart from sepsis; and (5) cases of thrombosis and sepsis combined. He came to the following conclusions: (a) the form which he calls thrombotic is the common variety after delivery, and not the brawny white leg, which is rare; (b) in such thrombotic legs there are not necessarily signs pointing to sepsis, and such thrombosis is rather a blood change associated with or due to severe loss of blood at the time of delivery; (c) the thrombosis in most cases starts primarily in the uterine and pelvic veins; (d) such thrombotic legs are not brawny and white, but dusky in colour and oedematous, invariably painful, with definite "tender spots," and the femoral or saphenous veins are constantly felt to be thrombosed; (e) both legs may be affected, but always one after the other; (f) the onset of the disease is from about the tenth to the twentieth day; (g) pyrexia is the rule for a variable period, but does not necessarily indicate sepsis; (h) such cases run a definite course lasting from about six to eight weeks; (i) complications are uncommon—pulmonary embolism is the greatest danger; (j) the prognosis as regards life is good; and (k) the prognosis as regards the leg itself is not good; frequently it regains its normal condition, but in many cases it remains permanently damaged.

Dr. P. HORROCKS did not think that there was any evidence that some cases of thrombosis occurred apart from sepsis, and that others were cases of thrombosis and sepsis combined. If the increased coagulability of the blood due to excessive hæmorrhage were the cause the thrombosis ought to occur at the time of the labour, when the bleeding took place, and when the coagulability was at its highest point; it also ought to occur on both sides and perhaps in other parts of the body, whereas it was well known to affect one side only as a rule. To say that there was no evidence of sepsis, in the sense that there was no perimetritis or parametritis, was limiting the word sepsis to a very narrow meaning. In the most fatal form of puerperal fever there was, as a rule, no clinical evidence of either para- or perimetritis, and yet it was undoubtedly a septic disease. He believed that both of these classes (Nos. 4 and 5) were septic in origin, and he was not convinced that the microbe was different in the two sets. He believed that they were septic on the following grounds: (1) the left side of the cervix was more frequently torn than the right, and this would lead to septic infection on the torn side; (2) there was a more or

less definite period of two or three weeks before the onset of the disease, which might be due to incubation; and (3) there was always more or less pyrexia, which could not be explained away on the hypothesis of mere clotting. Possibly ere long the microbe might be detected, and the differences might prove to be due to the relative amounts of vein or of lymphatics involved.

Dr. HERMAN suggested that the classification really had reference to "swelled leg," for some of the conditions included in it were not "white leg" and had never had this name applied to them. He agreed with Dr. Roberts in thinking that the disease commonly called white leg was not septic; if septicæmia was present as well it was a complication. He knew of no evidence that white leg had anything to do with septicæmia; but in the absence of information as to the comparative frequency of white leg before and after the introduction of antiseptics, or as to its bacteriology, it was not possible to be certain. He did not see in the table of cases any statement of the duration of the disease before the patient's admission into hospital. Possibly in some of them the non-pitting stage had been passed through before admission. He did not think that oedema from thrombosis was the same thing as the phlegmasia alba dolens the classical description of which was given by White of Warrington, afterwards of Manchester. He (Dr. Herman) was accustomed to teach that the solidity of the oedema in that disease was due to plugging of the lymphatics. No anatomical evidence of this existed; but there were good clinical reasons for that opinion. In lymphangitis extending up a limb from a poisoned wound the strip of inflamed lymphatics had the same brawny feeling as the whole limb had in phlegmasia dolens. In elephantiasis the lymphatics were known to be plugged, and the result was solid oedema like that of phlegmasia dolens, but persistent, and therefore leading to further changes in the limb. He had not understood Dr. Roberts to say that hæmorrhage caused phlegmasia dolens, but that it favoured it, which was, as he thought, undeniable.

Dr. AMAND ROUTH said that perhaps if Dr. Roberts had seen the cases in an earlier stage he would have found them more typical of "white leg." He had seen two cases where the initial symptoms were very severe but very transient—one quite recently in a patient who had nearly lost her life from post-partum hæmorrhage. On the third day she suddenly had acute pain in the left calf, and when seen three hours later had a temperature of 101.6° F., and the calf was swollen, with a circumference of two inches more than the right leg. The calf was quite white, extremely tense, glistening, and did not pit, and it had, in short, all the recognised signs of true phlegmasia dolens. Next morning the calf was less swollen, less white, and pitted, but the pyrexia remained, and on the tenth day the right leg became similarly affected. When the swelling and pain begin in the calf, and the femoral vein is free from tenderness and induration, it is obvious that any thrombosis which may exist in the popliteal vein has not occurred by extension of thrombosis. There can be no doubt that hæmorrhage is one of the elements in the causation of these cases, but why thrombosis should occur after the lapse of some days and not at once was difficult to explain. It was not easy to explain the presence of pyrexia, with perhaps an initial rigor, unless there was some sort of "sepsis" as another element in the cause of the lymphangitis, or, at all events, the blocking of the lymphatics, which so often was the first sign in these cases.

Dr. MACNAUGHTON JONES believed that the symptoms of phlegmasia dolens depended on the relative primary and secondary invasion of the veins or lymphatics and on the degree of cellulitis present. He thought that pressure did account for the disease in certain cases. He denied that sepsis alone was a cause, and attached no importance to the fact that the injury of the cervix was more commonly on the left side, but thought that there were anatomical reasons for the left leg being the one more commonly affected. "Painful spots" were not peculiar to any form of phlegmasia. High temperature was not to be taken as evidence of sepsis, as it occurred in various other post-partum conditions.

Dr. GRIFFITH said that Dr. Roberts's paper emphasised the distinction between true phlegmasia dolens and simple thrombosis. Hæmorrhage complicating labour was undoubtedly a very important factor in the causation of white leg, but the objection urged by Dr. Horrocks against its being the essential cause—namely, the considerable interval which elapsed between it and the appearance of the characteristic symptoms—applied with equal force to the theory of septic infection which he advocated. Thrombosis in both forms

of the disease, as a rule, started from the uterine veins and extended gradually to the common iliac, and it was not surprising that acute symptoms should arise when this great channel was blocked, nor was it necessary to suppose a further cause for them.

Dr. ROBINSON drew attention to the researches of Widal into the microbic origin of certain cases of phlegmasia dolens. This observer had found the clots in the thrombosed veins to be infiltrated with chains of cocci, probably streptococcus pyogenes. The walls of the veins had also been invaded by these organisms. Other observers considered that the bacillus coli communis played an important part in the causation of this morbid condition.

The PRESIDENT thought that Dr. Roberts's proposed classification was open to criticism; for instance, "cases due to pressure" (Class 1) might also be cases of "thrombosis apart from sepsis" (Class 4). Again, "cases associated with general disease" (Class 2) might also be "cases of thrombosis and sepsis combined." It would make it clearer if an instance of each type were given. A curious fact in the group of cases here recorded had not been referred to—viz., that three out of the four cases of double white leg (Cases 5, 8, and 10) began in the right leg. This was probably a coincidence, and might not appear in a more extended series of cases.

Dr. GILES noticed that in only one case—No. 14—was there undoubted sepsis, and it was the only one in which delivery was not at term; he thought that this was evidence that the ordinary white leg was not due to septicæmia. The reason assigned by previous speakers to account for the greater frequency of attacks in the left leg was not valid, inasmuch as injuries to the cervix would involve the connective tissue of the pelvis rather than structures so far off as the veins of the leg, whereas in nearly all Dr. Roberts's cases the pelvis was unaffected.

Dr. ROBERTS, in reply, said that he could not regard all cases of thrombosis as septic, pyrexia not necessarily indicating sepsis, and the onset of septicæmia being much earlier than it was in the kind of cases he had described. He thought that thrombi might be present in the veins of the broad ligaments without giving rise to physical signs in the pelvis. Probably extension of the clot either across the vena cava or the broad ligaments explained the implication of the other leg at a later date. In answer to Dr. Amand Routh, he had to explain that five out of the sixteen cases in the paper had been seen from outset to finish. He was sorry he could not specify the presentation in each of his cases, as this was not mentioned in the records from which they were taken.

The following specimen was exhibited:—

Dr. AMAND ROUTH: A Fetus the subject of Anencephalic Diprosopia.

OPHTHALMOLOGICAL SOCIETY.

A New Operation for Ptosis.—Blood-staining of the Cornea.—Sudden Severe Hemorrhage from the Conjunctival Surface of the Lid.—Exhibition of Specimens.

AN ordinary meeting of this society was held on May 2nd, Dr. D. ARGYLL ROBERTSON, President, being in the chair.

Dr. MILES brought before the society a New Operation for Ptosis. It was first described by him at the last International Congress of Ophthalmology at Edinburgh in August, 1894. He now gave the results of his further experience of its effect. The principle of the operation was to substitute the frontalis muscle for the levator palpebræ by extending the former muscle to the margin of the lid by a permanent wire suture. Two needles with eyes near their points were passed deeply through the frontalis tendon over the eyebrow, and their points brought out at the margin of the lid behind the lashes, taking up a substantial part of the tarsal cartilage on their way. A piece of silver wire was threaded through each needle, which was then withdrawn, leaving the loop of wire passing from the brow to the edge of the lid and back to the brow again. This was then tightened until the lid was sufficiently raised, the edge of the lid being slightly grooved by an incision to allow the wire to sink into the substance of the lid. One end of the wire was then passed under the skin and made to emerge by the side of the other end of the wire. The two ends of the wire were then twisted on each other until the lid was raised permanently, the ends were cut off, and the wire allowed to sink below the level of the skin. The skin at this point and at the lid margin healed over the wire, which remained permanently fixed in the substance of the

lid. From further experience it was found that the wire remained in position without causing irritation; the lids could be closed, and remained closed during sleep. All kinds of wire had been tried, but it had been found that silver wire was the most satisfactory. It was necessary to note at the time of the operation the situation of the twisted end of the wire in case it became necessary to remove the suture afterwards.—The PRESIDENT drew attention to the correct principle of the operation in forming so direct a connexion between the frontalis muscle and the lid. He apprehended some trouble from irritation if the wire was left in for any length of time; it might also, he conjectured, cut its way through the tarsal cartilage or the muscle above, and so lose its effect. Former methods of remedying this defect were, he thought, unsatisfactory. The operation introduced by Snellen was too complicated; Eversbusch's did not answer in severe cases, though it served well in slight ones; and that advocated by Panas was disfiguring and involved too extensive interference; the methods of operating with thread were, he thought, inefficient.—Dr. BRAILEY thought that in performing this operation it would be easier to introduce the needles from the lid margin, though he himself was content to use thread.—Mr. DONALD GUNN suggested that by passing both needles through an aperture over the brow the angle in the course of the wire would be avoided.—Mr. Spencer Watson, Mr. Lawford, Mr. Cartwright, and Dr. Ernest Clarke also discussed the relative merit of the operation.

Mr. TREACHER COLLINS read a paper on Blood-staining of the Cornea. He found that this staining of the cornea, which was of a greenish or reddish brown colour, was due to the presence of a number of highly refracting granules scattered throughout its substance. These granules were not located with any definite relation to the spaces between the lamellæ of fibrous tissue; they agreed in their spectroscopical appearances and chemical reactions with hæmatoidin. He found that in some of the cases associated with granules of hæmatoidin there was a substance which gave iron reaction with ammonium sulphide, and which was probably hæmosiderin. In eyes in which this discolouration occurred the tension was generally increased, the exit of fluid through the angle of the anterior chamber being obstructed by the accumulation of blood clots. He was of opinion that at first hæmoglobin passed into the cornea from the anterior chamber through Descemet's membrane, and that the hæmatoidin, which is insoluble in the fluids of the cornea, was then precipitated there. The whole of the cornea was at first affected, and when this was the case the condition could not be distinguished from that in which blood clots completely filled the anterior chamber. The absorption of the hæmatoidin granules commenced at the periphery equally in all directions, so that by degrees a narrow ring of clear cornea appeared around the stained area. The appearances then presented were strikingly similar to those of a lens dislocated into the anterior chamber. The absorption of the granules becomes slower and slower the further they are removed from the sclero-corneal margin. He had seen one case in which the discolouration had completely disappeared in the course of about two years.—Mr. JESSOP described a case recently under his observation in which, after an injury to the eye, the anterior chamber was half filled with blood, which also occupied the interstices of the cornea and which disappeared in three days.—Mr. COLLINS, in reply, distinguished between the cases he described and that mentioned by Mr. Jessop, which was an instance of only temporary transudation into the cornea.

Mr. W. H. JESSOP read notes of Sudden Severe Hemorrhage from the Conjunctival Surface of the Lid. A woman aged twenty-seven was taken to St. Bartholomew's Hospital in a state of collapse from repeated attacks of bleeding from the left eye. When seen the pulse was 130, small, irregular, and difficult to count; the extremities were cold and the right pupil dilated. On evertng the lid there was found a small, jagged-edged ulcer about 1½ mm. in diameter in the middle of the palpebral conjunctiva, from which bright arterial blood was flowing. The ulcer was burned by the actual cautery and treated with cold compresses. With one slight exception it gave no further trouble. Fourteen years before the patient had had erysipelas of the eye and nose on the left side, since which time the lid had been slightly swollen. There was no history of severe hemorrhage or of hæmophilia, and there had been no accident. The patient had been married twelve months and had been pregnant seven months. The case was probably of nævoid origin, but it differed from the cases previously described by there being no marked sign of vascular

tumour. There had been only three cases described, but none of them had been quite like this one.—Mr. SYDNEY STEPHENSON described a case recently under his care of a girl aged eleven upon whom the operation of expression had been performed for trachoma. This was followed by spontaneous attacks of bleeding from the lid, which occurred off and on for more than five months. Though repeated examinations had been made directly the hæmorrhage was observed, he had not been able to detect the point from which it came; there were general redness and turgidity of the conjunctiva, and the closeness of the observation precluded the possibility of malingering. There was no anaemia, purpura, or scurvy, and the removal of a premolar tooth had not led to any unusual hæmorrhage, so that hæmophilia did not seem probable, though there was a history of swelling occurring three times, and lasting some days, in the knee-joints.

The following living and card specimens were shown:—

Mr. DONALDSON: Microscopic Specimens of Alveolar Sarcoma of the Cornea.

Mr. MARCUS GUNN: Symmetrical Spontaneous Dislocation of both Lenses.

Mr. MORTON: (1) Tumour of the Right Malar Region, probably Sebaceous; and (2) Persistent Hyaloid Artery.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Antipyretics, their Use and Abuse.—The Recognition and Treatment of Peripheral Neuritis.

A MEETING of this society was held on May 3rd, Dr. BANNING, the President, being in the chair.

Dr. WILLIAM HUNTER read a paper on Antipyretics, their Use and Abuse. He pointed out that the extent to which antipyretic agents were used and their manner of employment were greatly influenced by our views of fever. In its simplest aspects, as it presented itself in the lower animals, fever might be looked upon as a reparative process, but in man, owing to the higher organisation of his nervous system, it greatly lost this character, and the febrile process invariably tended to be much in excess of any possible requirement and to become a source of danger. After considering the analgesic properties of the more recently introduced antipyretics derived from coal-tar products, such as antipyrin, phenacetin, and antifebrin, he remarked that the control of the nervous system was one of the principal desiderata in the treatment of fever. The proper object of such drugs was, however, not to abolish fever by a summary process, as was at first expected and attempted, but rather to bring the febrile process within reasonable limits. More particularly in severe sthenic cases, where the temperature rose above 104°F. and was likely to rise higher, it was desirable to reduce the temperature 1° or 2°. The administration of these remedies should always be cautious, more particularly in the case of antifebrin, the dose of which, as given in books (3 to 10 grains) is much too high; it ought rather to be from 1 to 3 grains. Their best effect is obtained when cold sponging is employed as an adjunct.—The PRESIDENT had found that no antipyretic equalled, either in efficiency or in safety, the use of cold sponging and wet packs.—Dr. SYMONS ECCLES believed that the direct action of antipyrin, though commonly considered to be stimulant to the heat centres, could also be attributed to its reducing qualities, removing oxygen from the protoplasm of the nerve cells, and thus diminishing activity and producing analgesia. He could not altogether agree with Dr. Hunter that the high temperature of man is of nervous origin and peculiar to him; he believed that animals suffered also from nervous manifestations, which might be due to excessive oxidation produced by nature in order to get rid of leucocaines or other toxins. In neurasthenia the rise and fall of the tide of leucocaines in the blood coincided with the periodical attacks of depression, malaise, and all the vague but real discomforts felt by neurasthenics. He thought that toxæmia would in the future be regarded as a probable, if not a constant, factor in functional nervous disorders.—Dr. ATKINSON had not found any benefit to follow the use of antipyretics, and thought that, as the temperature always fell before death, high temperature by itself would not kill a patient.—Mr. MACADAM ECCLES referred to surgical cases

where high temperature was due to nerve influence, alluding specially to cases of head injury followed by high fever without sepsis, and to so-called catheter fever. He pointed out that after injuries of the head the temperature was often different on the two sides.—Dr. HUNTER replied.

Dr. CAGNEY read a paper on the Recognition and Treatment of Peripheral Neuritis. He quoted cases to show that in many instances of alcoholic neuritis there was a danger of administering alcohol for the relief of symptoms which were in reality due to that poison. He discussed some points in the causation of neuritis and cited cases showing a remarkable individual susceptibility, both inherited and acquired. He maintained that a combination of toxic states was most often the probable cause of neuritis, and quoted illustrative cases. He urged that in view of the great importance of the early recognition of peripheral neuritis, and the certainty of detecting it in all cases where the motor system was involved, every medical man ought to make himself familiar with the very simple methods of electro-diagnosis.

LIVERPOOL MEDICAL INSTITUTION.

Enterostomy for Foreign Bodies.—Two Cases of Compound Depressed Fracture of the Skull.—Trephining for Subdural Hæmorrhage.—Eye Cases.—Painful Digestion in Chlorotic and Hysterical Persons.

A MEETING of this society was held on May 2nd, the President, Mr. CHAUNCEY PUZZEY, being in the chair.

Dr. ALEXANDER related a case where he had performed Enterostomy and had removed a very large number of plum and other fruit stones from the lower part of the ileum, close to the cæcum.

Mr. ARTHUR WILSON read notes of Two Cases of Compound Depressed Fracture of the Skull.

Mr. DAMER HARRISON related a case where he had successfully Trephined for Subdural Hæmorrhage. For many months the patient was unable to talk or to express himself by writing, but he ultimately made a good recovery.

Mr. BICKERTON showed a man on whom he had performed Mules' Evisceration Operation, and another patient from whose eye he had removed a piece of glass three-quarters of an inch long.

Mr. GEORGE WALKER showed several patients illustrative of the treatment of Posterior Adhesions of the Iris, the synechiæ having been separated from the anterior capsule of the lens by means of an ordinary cataract needle.

Dr. GLYNN read a paper on the Painful Digestion common in the Hysterical, and its Diagnosis from Gastric Ulcer. He pointed out that the symptoms (pain, especially after food, perhaps relieved by vomiting, and occasionally hæmatemesis) were met with in merely functional disorder as well as in ulcer of the stomach. Many of the cases of either disease were relieved by a course of milk and lime-water, so that the test of treatment failed to be of any assistance. He pointed out that nervous dyspepsia of the hysterical was very frequently met with in the chloro-anæmic, and stated that he had found that the chlorotic were almost invariably hysterical, and that they presented the stigmata of hysteria, including restriction of the visual fields. He considered the various pains and hyperæsthesia the chlorotic suffered from were due to the hysterical condition. The most convenient indication of hysteria to be sought for in the preliminary investigation of a suspected case was tremor of the eyelids. The few chlorotic girls who betrayed no symptoms of hysteria did not, as a rule, suffer from neuralgias and painful digestion. He discussed certain symptoms of nervous dyspepsia—the character of the pain and its relation to the ingestion of solids and liquids, and compared them with those of gastric ulcer. The diagnosis of the dyspepsia of the chlorotic and hysterical from the dyspepsia associated with gastric ulcer was rendered especially difficult as the latter affection was also so frequently accompanied by hysteria and chlorosis. He considered it likely that the pain which often attended gastric ulcer was due to the fact that this lesion often co-existed with hysteria and hysterical neuralgias, more especially when the patient was exhausted and anxious. In the case of latent ulcer, where the earliest symptoms were hæmatemesis or the signs of perforation, the patients were usually in good health. He considered that the nervous dyspepsia he

described was a hyperæsthesia of the stomach, best treated by general measures and not by drugging.—Dr. A. C. E. HARRIS agreed with Dr. Glynn in distinguishing anemia from chlorosis. It was in the latter class that painful digestion was met with, but only in about a third of the cases, and that among those who did hard manual labour. He considered the gastric pain to be due to hyper-acidity and benefited by alkalies; in fact, the success of Bland's pills and capsules at first is probably due to the potash they contain. If the gastralgia does not yield to Bland's treatment, larger doses of alkali remove the pain and then iron completes the cure.—Dr. HENRY HEAD accepted Dr. Glynn's classification of painful digestion, and pointed out that it included all those cases where food caused pain, mostly associated with tenderness in the superficial structures of the thorax, abdomen, and back over the areas of the sixth, seventh, eighth, and ninth dorsal segments; but disturbance in any other organ also supplied from these segments will cause the ingestion of food to be painful. Thus rapid implication of one base of the lung (as in tuberculous phthisis) or rise of pressure in the left auricle (as in mitral stenosis) will cause pain and tenderness of one or more of these areas, increased by the ingestion of food. Excluding these reflex gastralgias, we find a great group with gastric ulcer at one pole and anorexia nervosa at the other, with the gastralgia of chloro-anæmia as an intermediate link.—Mr. YOUNG and Dr. GILL also took part in the discussion on Dr. Glynn's paper.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Infantile Convulsions.—Toxic Affections of Vision.—Apparatus for the Administration of Anæsthetics.—Exhibition of Case.

A MEETING of this society was held on May 1st, Dr. TEW, President, being in the chair.

Dr. FENNELL read a paper entitled "Some Observations on Fifty-nine Cases of Infantile Convulsions." He remarked on three points which did not tally with the opinions laid down by acknowledged authorities—viz., that two of the above cases appeared undoubtedly to be caused by roundworms; that in four the pupils were extremely contracted; and that only two presented any symptoms of rickets.—Remarks were made by the President, Dr. Ransom, Dr. Hunter, and Dr. Watson.

Dr. LAWS read a paper on Toxic Affections of Vision. The clinical features of a case of toxic amblyopia were first described, together with the methods of testing for the central scotoma; and it was remarked that the progress of the disease followed the course of development of the visual functions, the more specialised being the earlier attacked. After a short historical sketch of the researches that had been made on the subject since the publication of Mackenzie's work in 1830, the pathology of the affection was discussed, with especial reference to the question of whether the lesion in the optic nerves was of the nature of an interstitial inflammation or a primary degeneration of nerve fibres with secondary overgrowth of connective tissue. Adopting the latter view, Dr. Laws pointed out the analogies of the process with the system diseases of the spinal cord, and particularly with tabes; in both an afferent tract of fibres, marked out by its function and development from those among which it lay, was affected by degeneration, and in both a certain tissue liability was indicated by the existence of a hereditary form of the disease; the cause in the one case being a chemical poison circulating in the blood, while in the other there was no inherent improbability in the view that it might be a toxæmia. After some remarks on the differential diagnosis of toxic amblyopia Dr. Laws concluded by urging that in cases of pallor of the discs and suspected chronic disease of the nervous system the very simple test for a central colour scotoma should be included among the methods of investigation.—The President, Dr. Ransom, Dr. Kingdon, Mr. Macmillan, and Dr. Tresidder discussed the subject.

Dr. BELL TAYLOR exhibited a new Apparatus for the Simultaneous Administration of Ether and Nitrous Oxide Gas.

Dr. BELL TAYLOR also showed a man upon whom he had previously operated for Cataract before the society.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Palliative Treatment of Jaundice caused by Malignant Obstruction.—Probable Lesions in Incipient Caseous Pulmonary Phthisis.—Exhibition of Cases and Specimens.

THE ninth meeting of this society was held on May 1st, Dr. CLOUSTON, President, being in the chair.

Dr. WILLIAM RUSSELL read a paper on the Palliative Treatment of Jaundice from Malignant Obstruction. He narrated the case of a patient eighty-five years of age (but looking considerably younger), who in the early part of 1894 began to suffer from slight dyspeptic symptoms, accompanied with a suspicion of jaundice. The jaundice was at first ascribed to obstruction from duodenal catarrh, but did not yield to treatment. After a time palpation of the abdomen revealed an elongated structure, somewhat firm, tough, and resistant, which lay over the aorta, and was believed to be the pancreas. There seemed to be no implication of the pylorus in the disease. The liver was slightly enlarged, but otherwise normal. The distended gall-bladder was felt as a pyriform elastic body in the axillary line immediately under the tenth rib. The patient complained of a general sense of malaise, aversion to food, and continuous nausea. Operation was suggested in the hope of relieving the symptoms, but the patient declined. Having remained much in this condition for three months, with her strength gradually failing and the discomfort continuing, she became anxious to submit to any operation which might alleviate her symptoms, and was accordingly removed to Mr. Cotterill's ward in the Edinburgh Royal Infirmary. The case was believed to be malignant disease of the head of the pancreas without any implication of the stomach or liver; it was considered that there was no occlusion of the cystic duct, and so to tap the gall-bladder would effectually drain the retained bile. Mr. Cotterill accordingly operated. The patient lived for thirty hours. It was doubtful if she would have lived longer had she not been operated upon. At the necropsy the diagnosis was confirmed in every detail. The case raised the important question whether the operation might be regarded as legitimate, being merely a palliative measure. To operate for the removal of calculi was legitimate and necessary. Dr. Russell thought that it was justifiable to operate in the hope of relieving the misery and discomfort of a deepening cholemia, and that the present operation was as humane a proceeding as tracheotomy in malignant laryngeal disease. Had the operation been performed when first suggested the patient might have been alive still. If the stomach were involved and gave rise to prominent symptoms he did not think the operation would afford sufficient relief to warrant its performance. Even obvious implication of the liver would not necessarily be a contra-indication so long as distension of the gall-bladder showed that the hepatic duct was not blocked.—Mr. JOSEPH BELL remarked that Dr. Russell's paper was short, accurate, and descriptive, and supplied food for thought. He agreed that an endeavour should be made to relieve such cases.—Dr. GIBSON had watched a similar case on which a colleague had operated. The relief after operation was very great indeed. It had been stated that drainage of the entire bile from a patient for his natural life did no harm in a case which had been operated on for non-malignant stricture of the biliary canal.—Mr. HODSDON raised the question whether in cases of malignant jaundice it was not safer simply to drain the gall-bladder than to perform cholecystenterostomy.—Dr. LEITH gave an account of the post-mortem examination and made some remarks.—Dr. RUSSELL replied.

Dr. R. F. C. LEITH read a paper on the Probable Lesions in a case of Incipient Caseous Pulmonary Phthisis of over four years' duration, with no physical signs, but with abundant bacilli in the sputum, together with some remarks on their diagnostic and prognostic value. The patient, a man forty-three years of age, sought advice on account of a hydrocele. He had a slight cough, especially in winter, but his general condition seemed very good, his height being five feet ten inches and his chest measurement thirty-three inches and a half during expiration, expanding three inches during inspiration. His chest showed no physical signs of disease, but on staining some of his sputum, which seemed to consist entirely of transparent sticky mucus and was small in quantity,

numerous tubercle bacilli were found, presenting almost the appearance of a pure culture. As no physical signs could be discovered in the chest and as there was slight huskiness of the voice, primary laryngeal tuberculosis was suspected, but the laryngoscope showed the parts to be normal. After a month's holiday in the country the sputum almost entirely disappeared, and there was only slight occasional morning cough. He remained much in this condition for the next two years. In February, 1893, the patient passed through an attack of acute appendicitis, and while convalescing from this the chest condition made considerable progress. The sputum increased in amount, became purulent, and prolonged expiration with numerous moist sounds were observed in the second interspace on the right side close to the sternum. The patient was sent to Torquay for three months, where he made very rapid improvement and increased in weight, the sputum diminished, the signs in the lungs disappeared, and he is now in good health, being able to walk from twenty to thirty miles, and enjoying amusements in moderation. The sputum still contains bacilli. To all intents and purposes he is as well now as he was four years ago. Dr. LEITH discussed the case at considerable length and dwelt on the frequency with which cicatrised tuberculous lesions were found in the lungs after death. In about 1400 post-mortem examinations in the Edinburgh Royal Infirmary he had noted such lesions in about 12 per cent. of the whole. In the present case he considered, from the large number of bacilli present in the sputum, that there was probably cavity formation in the lung. He discussed the importance of the tubercle bacillus from a diagnostic and prognostic point of view.—Dr. PHILIP thought the paper contained three main points of interest—viz., the abundance of the tubercle bacillus, the relative duration of the case, and the comparative absence of physical signs. He thought they could enumerate a large number of cases lasting, not four years and a half, but ten or twelve years, when the course was very chronic. In many cases there were few physical signs for the first five, six, or seven years.—Dr. RITCHIE and Dr. CLOUSTON having spoken, Dr. LEITH replied.

Dr. LEITH showed a case of Caseating Pulmonary Phthisis of four years' standing. The patient formed the subject of the paper which had just been read.

Mr. A. G. MILLER showed a man whose Arm had been amputated through the Elbow for Cancer of the Hand and Forearm.

Dr. LUNDIE and Mr. ALEXANDER MILES showed cases of Skin Grafting from the lower animals.

Dr. W. ALLAN JAMIESON showed a case of Impetigo Varioliformis; a case of Erythema Perstans; a case of Exfoliative Dermatitis limited to the Hands and affecting to a slight degree the sides of the Feet in a man with general but mild Ichthyosis and Hyperidrosis Pedum; and a case of Scorbatus.

Dr. LEITH exhibited the Temporal Bone of a girl fifteen years of age who died from Cerebral Abscess. The middle ear was caseous, and the tympanic membrane, which showed a perforation, was ossified.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Defective Infantile Life Unrecognised by State Medicine.—Private Hospitals or Home Hospitals.

A MEETING of this section was held on April 19th, Dr. T. W. GRIMSHAW being in the chair.

Mr. WALTER BERNARD of Londonderry read a paper on the subject of Defective Infantile Life Unrecognised by State Medicine. He argued that it is the duty of the State to foster every movement and encourage every effort to disseminate knowledge in diagnosing those conditions of society which are unfavourable to true national progress. General medical practitioners having done more successful work in the prevention of insanity and abnormalities than any other medical or social organisations, they are the earliest and most efficient observers of the abnormal in infantile life. Each stage of mental growth ought to be carefully investigated, not by far-reaching researches, but by domestic clinical work and family and personal histories, through which only can a practical psychology of infant and

child life be attained. The primary object to be attained is to teach the importance of order, thrift, and cleanliness in the management of feeble children. Contractures and arrests of development are generally associated with an enfeebled and easily disturbed nervous system. In such cases the enfeebled senses obtain much unconscious guidance and perfection by the exercise of the muscles of the deficient or rigid limb, the latter more especially by posture, as in the Gower methods. Consequently, in a minor degree, a kindergarten and gymnasium are indispensable in the household. Hygiene in the home is essential, opening up the way to clearer ideas on the subjects of infant sanitation and infant life. The principles which suggest early promptitude in detecting, arresting, and dealing with mental imperfections in infantile life are not sufficiently recognised by State measures. If the family medical attendant's hands were strengthened by a system of jurisprudence framed, confirmed, and recommended by State medicine, it would tend to improvement in the formation of character in the initial stages of existence.—Dr. J. W. MOORE said that the Academy owed a debt of gratitude to Mr. Bernard for bringing forward this subject. Within the last decade or two there had been a wonderful change regarding the value put on the life of children, and the death-rate among young children had been steadily falling. In the great cities there were many philanthropic associations whose sole object was the improvement of childhood, such as Mr. Barnardo's in London.—Sir W. STOKES referred to the importance of educating people, and this more particularly in Ireland, to a better knowledge of how to cook their food. He believed that one of the main causes amongst the poorer class of having recourse to the public-house was the want of properly cooked food in their homes. A great many physical and mental troubles were due to intemperance.—Dr. NINIAN FALKNER said there were two defects possible in infantile life, one physical, and the other mental. Referring to the mental impressions received during childhood, he considered that a great many of the unfortunate careers of men and women were due to immoral suggestions made to them in their infancy by nurses.—Dr. RAINSFORD said he had had three years' experience in a very large lunatic asylum, and thought that the early training received in childhood had a great effect on the after-life of the individual. Considering the manner in which children are brought up in large cities, it is a marvel that criminals are not more numerous.—The CHAIRMAN regretted that medical men were not taught to advise as to the bringing up of children. If children are not looked after much harm is done both to them and to their children, if they ever have any. There was no doubt that infants could be educated from the cradle. With regard to the question of nurses, referred to by Dr. Falkner, he thought great damage, both physical and mental, was done by them. The practice of lying was learnt in the nursery. These evils were produced by the mothers paying others to do what they should do themselves. In almost every instance in which the Society for the Prevention of Cruelty to Children, of which Dr. Rainsford was the medical officer, proposed to start a branch in any town, they were met with the reply that they knew how to take care of their children. The clergy were especially strong in this opinion. The introduction of the School Board system into England has had the effect of catching a great number of street arabs. There were two institutions in Dublin—one Protestant and the other Roman Catholic. The reports of these institutions were of the most encouraging kind. With reference to cookery, he had heard the following anecdote. A parish priest went to a house about dinner hour and asked when the man would be in, and was told "Presently." He asked the wife where the man's dinner was. She replied, "In the press," where there were cold meat and potatoes. On further questioning, she said that it had been cooked for two or three days. This was the way in which the husband was treated when he came home. The number of uncertified deaths in Dublin was appalling. It meant either that a medical man was not called in at all or that he was called in so late that he was not able to give a certificate of the cause of death.—Mr. BERNARD, replying, said the Jubilee nurses had been the means of enabling ladies to visit the poor people and teach them cooking, thrift, and cleanliness. If rules were formulated by the State insanity would be diminished. The lower classes carry out the rules as well as the upper classes.

Dr. J. W. MOORE read a paper entitled "Private Hospitals or Home Hospitals." He said that the institution and administration of a private hospital call for the exercise of

exceptional mental and bodily powers, and are quite incompatible with the practice of the medical profession. Such establishments should be subject to inspection by the sanitary or some other responsible authority and should be conducted on sound financial principles. The term "home hospital" is better than private hospital, the object being to provide for the sick a home where they will be cared for by skilled hands under the direction of their attendant physicians or surgeons and amid the best possible surroundings from a health point of view. A "home hospital" should be a detached building, heated, ventilated, and lighted on the most approved lines, and specially constructed for the purpose on an eligible site. The sanitary arrangements should be above suspicion. It should be licensed and freely open to periodical and systematic inspection by the sanitary authorities of the district in which it stands. It should be managed by a committee the members of which would inspire confidence and command respect, and to which the officials would owe allegiance. Its finances should be controlled by this committee, and a report and statement of accounts should be published at least once a year. If all this were done private hospitals would be worthy of the name, and in them persons of refinement and culture might, when suffering from sickness or injury, enjoy the advantages of medical or surgical care and good nursing together with that privacy and quiet which in such cases so largely conduce to comfort and even to recovery.—Sir W. STOKES regretted that he could not agree with much of what Dr. Moore had said. He had had experience of no less than five of these hospitals, and while admitting the importance of having the best hygienic surroundings possible he did not think that these institutions deserved the very severe strictures made upon them. If they were so bad they would long since have ceased to exist. He had treated many important surgical cases in them and had never heard any complaints. Many of the largest institutions in London, as St. Bartholomew's and University College Hospitals, were situated in densely populated localities. Inspection did not do any good, and it would take away the privacy of the hospitals.—Dr. PARSONS said they had to make the best of what they had. The patients had far more quietness in these hospitals than in their own homes. He did not think that they should be inspected. If they were not properly kept medical men would not send their patients to them. These hospitals were very useful for treating patients who were too well off to be treated in an ordinary hospital.—Mr. SAVAGE had had some medical cases in a private hospital and was very much displeased with the treatment they received. There was nothing to be gained by sending medical patients to these "home" hospitals. He thought Dr. Moore would have spoken more of "home" hospitals for infectious diseases. During epidemics (as of scarlet fever or small-pox) they should charge a reasonable fee for these rooms and have whatever practitioner the patient wished to attend him.—Mr. THOMPSON said it would be difficult and expensive to get detached buildings. In some of these hospitals the attendance and nursing were very good, and everything was ready on the spot.—Dr. J. W. MOORE replying, said he granted that these hospitals were a necessity. He wanted them put on a sound financial and sanitary basis. Not long ago a partner in one of them told him that it did not pay. The sanitary authorities would very soon have to take the matter in their own hands. He could produce positive evidence that these hospitals are a growing scandal.—Mr. BERNARD said that there was a strong feeling in the north-west of Ireland that there were too many private hospitals in Dublin. Some of his own patients complained of the noise and insufficient nursing in them.

BRITISH MEDICAL BENEVOLENT FUND.—At the monthly meeting held on Tuesday, April 30th, the committee had to postpone the consideration of two-thirds of the cases before them owing to lack of funds. To applicants this means terrible disappointment and privation, as £30 per annum is considered a bar to assistance. The committee urgently press this deplorable position upon the attention of the more fortunate members of the profession, and ask for subscriptions or donations to enable them to meet this deficiency. Contributions may be sent to the Treasurer, 84, Brook-street, W.; to any of the officers; and especially to Dr. Samuel West, 15, Wimpole-street, hon. financial secretary.

Reviews and Notices of Books.

Descriptive Catalogue of the Pathological Specimens contained in the Museum of Guy's Hospital. Third Edition. Vol. I.: Morbid Conditions of the Respiratory Organs and Alimentary Tract. By LAURISTON E. SHAW, M.D. Lond., F.R.C.P., Assistant Physician and Curator of the Museum; and E. COOPER PERRY, M.A., M.D. Cantab., F.R.C.P., Assistant Physician and Demonstrator of Morbid Anatomy. London: J. & A. Churchill. 1894.

THIS catalogue, which must almost be looked upon as a third edition of a classic work, will be welcomed, not only by students, present and past, of Guy's Hospital, but by every active worker in pathology. The first edition, edited by Hodgkin, was published in 1829, whilst the second, edited by Dr. Samuel Wilks and the late Dr. Habershon, appeared in seven parts between the years 1857 and 1863. The editors of the present volume have somewhat altered the plan of the work, and have apparently given a large amount of time and care to the verification and correction of the specimens catalogued. They say "that the greater number of preparations described in this volume have been submitted to further examination and dissection before being remounted, and the descriptions given of them have almost in every case been rewritten upon a uniform plan. All references to post-mortem inspections have been verified, and, in the belief that the study of a pathological specimen is made at once more interesting and of more practical utility when combined with a study of the history during life of the case from which the preparation has been derived, clinical accounts have, wherever possible, been appended to the descriptions of the specimens, and where they were already given in the old catalogue they have in many cases been amplified." They have also examined microscopically many of the specimens which they considered were probably open to reclassification. Taking it altogether, the work is exceedingly well done. Each section includes a special part of the respiratory organs or alimentary tract; for example, in Section I. are given the Injuries and Diseases of the Larynx; in Section II., Diseases of the Thyroid Gland; in Section III., Diseases of the Thymus Gland; and in Section IV., Injuries and Diseases of the Bronchial Tubes; and so on through twenty-four sections, the last of which is devoted to Injuries and Diseases of the Peritoneum. At the head of each section is given a list of the groups of specimens—thus, congenital malformation, 1; eversion of sacculus, 2; injuries, 3 to 10; foreign bodies, 11 to 14—and so on through various groups, as examples of which may be mentioned tubercle, variola, typhoid fever, hypertrophy of muscles, polypus, carcinoma, &c. It will thus be seen that a regular plan has been adhered to throughout the work, and this methodical arrangement renders the catalogue exceedingly useful for reference, though it may interfere somewhat with its value for purposes of teaching. This, however, is very much a matter of opinion and depends frequently upon the method of teaching adopted. The work of description is most carefully and accurately done; the descriptions are not too long, and the detail is not too great, so that the attention is not distracted by insignificant details from the main features of the specimen under review. From the method of arrangement most of the references to the specimens are readily found, but we anticipate that to make them still more accessible the editors, on the completion of the catalogue, will find it well to give an index with full cross references. By doing this they would add greatly to the value both of the catalogue and of the collection. We congratulate the editors on the admirable scheme they have drawn up, and also on the way in which they have carried it out.

The Spirit of Cookery. By J. L. W. THUDICHUM, M.D., F.R.C.P. Lond. London: Baillière, Tindall, and Cox. 1895. Price 6s.

WE had read a great part of this book with much enjoyment, and had made up our minds from all we read, and also from the fact that both title-page and cover declare it to be "A Popular Treatise on the History, Science, Practice, and Ethical and Medical Import of Culinary Art," that it was not intended for the powers that be in our kitchens, but for their masters and mistresses, when a perusal of the preface showed us our mistake, for Dr. Thudichum says: "In the present treatise it has been attempted to produce such a system of general rules as will enable those who thoroughly master them to perform the principal culinary operations without reference to the frequently unintelligible records of the details of mere empiricism." As very few mistresses in these days can "perform culinary operations" without promptly receiving "notice" that the cook wishes to leave, the book must be designed for that functionary herself. We fear, however, that no cook, let her be ever so efficient, will understand Dr. Thudichum's English. There is no need for her to understand that she is a professor of the "magiric" art or science, but she is certainly very unlikely to do so, and what will she make of "soups characterised by molluscs and articulates," of "tritulating," or "volatilisng" an ingredient, or of the statement that "cooking destroys the toxicity of mussels," and will she know what is demanded of her when she is told to "communute" something in a mortar, or to do something "concurrently" with another? She may have some perception of what is meant by "overtoneing the weakness of a broth," but is she likely to have any idea as to what "the production of artefacts" may be, and will she not resent it when she finds that when making a boiled apple pudding she puts her apples into a paste made of flour and suet she is placing them in a capsule? As for Dr. Thudichum's definition of a pudding she would unhesitatingly laugh it to scorn. "A pudding is mostly, if we may be allowed to use an expression from petrology, a *breccia*—a compound formed of fragments of a material which had a previous independent existence, and bound together by a soft mortar or cement which was able to penetrate and fill the pores of, and intervals between, the lumps, and then become set by the culinary thermic process. It is by this that pudding becomes a unity and receives a kind of gustatory homogeneity, however numerous and diversified may be the substances introduced into its constitution." Alas for human cooks who have to master these hard sayings "concurrently with the preparation of the dishes" to which they refer—that is, if the book is meant for cooks. Alas for most mistresses if the burden is laid on them! Cooks and mistresses are but mortal, and, besides that, may have as much dislike to cumbrous, latinised, and gallicised English as we ourselves have. To "gratinate" is not a household word, and to find out what an "ensouped entrée" or an "inspissated broth" is, or how to add "a collateral consommé," or grasp the difference between "bottom heat, radiated heat, and conducted diffused heat" might cost more time and temper than either mistress or maid had at her command. If Dr. Thudichum had but written good, honest, straightforward English we should have had nothing left to desire. "The Spirit of Cookery" is full of information of every kind; men as well as women will delight in it, and no one can open it without finding something which he (or she) has always been longing to know. To a housekeeper in the true sense it will be simply invaluable.

Dr. Thudichum is severe on the delusion that bones and scraps can by good cooking produce excellent and nutritious soups; he maintains that this can only be done when due care has been taken to "*faire sourire le pot-au-feu*." He gives a good sketch of the historic

literature of cookery, enunciates excellent culinary axioms, and explains French culinary names. "*A la Gérard*," it seems, is a name sarcastically applied to a dish that is a failure, because a cook long ago prepared one which was to be set before Madame de Maintenon and called by her name, but prepared it so badly that he did not think it good enough to bear her name, and gave it his own. We are told a great deal about spices and condiments of all kinds. This part of cookery is to our mind of the most sad and sorrowful description; for so many dishes depend on a delicate adjustment of flavour, and cooks trust to rule of thumb and mother wit. A cook's thumb is clumsy, her palate blunted by frequent tastings, and she makes up a fierce and fiery compound and thinks she has done the whole duty of woman. What cook, too, would afford "*beef à la mode*" the indulgence prescribed by the "*Tabella Cibiaria*?" "It must be allowed to muse gently for several hours, inaccessible to the ambient air, and on the even and persevering heat of charcoal in furnace or stove. After having lulled itself in its own exultations and the dissolution of its auxiliaries it may appear at table with a powerful claim to approbation." Dr. Thudichum's sympathies are very properly all-embracing. "Frogs' thighs," he says, "yield a bland broth and are improved by the addition of snails"—vineyard snails, be it well understood—and he gives recipes for the *olla puchera*, and national dishes of all kinds. There is as much incongruity and variety in the composition of Joan Cromwell's "Grand Salad" as in the "various peoples, nations, and languages" over whom our Queen rules. "It is composed of equal parts of almonds, raisins, capers, pickled cucumber, shrimps, and boiled turnips. It may be made with cream, oiled butter some good jelly of meat, Florence oil, and flavoured with salad mixture, vinegar, lemon, and herbs." We are puzzled by a "Dunelm of mutton." It seems to be a more elegant haggis, but, though familiar with the ere-while Palatinate, we never heard of the dish. Nor is Dr. Thudichum quite accurate in his account of the making of the "griddle or girdle cake." Griddle, by-the-bye, is only the local pronunciation of girdle. Those who say griddle would also say girm for grin. A griddle cake is not "baked on the free fire," but suspended by the bow of the girdle to a hook above the fire. He is also wrong in saying "an inhabitant of an English town of the present time has probably little inducement to bake a griddle cake, but if he were to be transplanted to Central Africa, or the Brazils, or the Yellowstone regions he might perhaps draw some consolation and nutriment out of so simple a preparation of the gifts of Ceres." At this present time no well-to-do house in the north is without girdle cakes at tea—it would be a bitter disappointment were it otherwise, and they are made as delicacies in every cottage. The pitmen call them "singing hinnies" (hinny is honey, a term of endearment), the over-prudent call them "sudden death," but eaten in moderation they will, to use one of Dr. Thudichum's expressions, "molest no delicate stomach."

LIBRARY TABLE.

Schemata zum Einzeichnen von Gehirnbefunden. (*Diagrams for Cerebral Jottings.*) By Professor KALISKO and Dr. REDLICH. Leipzig and Wien: Franz Deuticke. 1895.—This is a small packet of diagrams of different aspects of the brain, so designed that the site and extent of a lesion can be readily and distinctly indicated. It contains an introduction illustrating the method of using it. From the appearance of the plates and the eminence and experience of the authors we have little doubt that pathologists and others will find them useful.

Manuel de Percussion et d'Auscultation. By Dr. P. SIMON. Paris: Félix Alcan, Éditeur.—This manual is an elementary introduction to the arts of percussion and auscultation.

dealing with them from their practical and their theoretical sides. Besides an account of auscultation of the cardiovascular and pulmonary system there is a chapter on Auscultation of the Digestive Tract, and also a full explanation of the uses of this art in obstetrical practice. The book should prove a useful aid to those working practically at these subjects.

Origen Polédrico de las Especies (Polyhedral Origin of Species). By ARTURO SORIA Y MATA. Madrid. 1894.—The author seems to have amused himself by making a number of four- and five-sided pyramidal figures in cardboard and crossing them in various ways so as to form what he calls betatetrahedra and pentatetrahedra of various forms, which he persuades himself have certain relationships with the sexes, with chemical bodies such as acids and bases, and also with musical notes and intervals and even with colours. The, to him, obvious connexion between the origin of the human species and the starfish is shown by drawing a child with its arms and legs stretched out so that the limbs with the head point to each of the five angles of a "dodecahedro-icosahedral closed chain," the axes passing through the child's umbilicus. After this we learn in a chapter headed "Genius and Madness" that the former is but a variation in the disposition and grouping of regular or healthy polyhedra, the latter being a grouping of polyhedra which are not perfectly regular, and at the end it is suggested that the change from venous blood to arterial and *vice versa* is probably merely a change of shape of the molecule from a dodecahedron to an icosahedron or the contrary.

MAGAZINES.

The Practitioner.—The current number of this publication is as interesting as usual. Its opening article is a carefully written account of the Schott method of treatment by Dr. John Broadbent, with remarks on the mode of action of the treatment by Sir William Broadbent. Following this is an eminently interesting article on the House in its Relation to the Prevention and Treatment of Disease. Unfortunately, though, as Dr. G. V. Poore, the author of the paper, remarks, his recommendations are mostly only possible when the house is surrounded by a certain amount of ground, and this in London is very difficult to obtain. Dr. Braithwaite writes interestingly about the relation between a lack of animal food and diseases of the female generative organs. The Medico-Literary Causerie deals with Medical Poets. Reviews, Notes of the Month, Pharmaceutical News, and abstracts from foreign journals complete the number.

Chapman's Magazine.—The latest addition to the number of monthly periodicals is a very notable one. Issued by the great publishing house of Chapman and Hall, under the able editorship of Mr. Oswald Crawford, *Chapman's Magazine* marks the beginning of a new era in periodicals. The contents are entirely fiction—dramatic fiction,—all eminently readable, and there are no illustrations. Mr. Bret Harte opens with the first instalment of a Californian story worthy of the creator of "M'liss," and Mr. Anthony Hope follows with four brilliant little social dialogues. Mr. Stanley Weyman contributes a little episode dealing with Henry of Navarre, and Mr. Brett a detective story which is exciting; but the deductions which the "country surgeon who made the post-mortem" draws are so comically warranted by what he is said to have found. Mr. James Payn has a good story of a ghostly "sell," and Mr. Frankfort Moore an amusing social sketch. The solitary lady contributor, Miss Violet Hunt, in the opening chapters of her serial, "A Hard Woman," fully bears out the good opinions she gained by her first novel, "The Maiden's Progress." Her light hand and delicate literary rhapsody-play are as conspicuous as ever.

The number ends with a poem by Mr. John Davidson. The get-up of the magazine is excellent in every way, and the cover artistic; only, if Mr. Crawford would induce his printer to fold the pages in a less exasperating way, it would be a relief to the reviewer who has to cut them; but the magazine is certainly a wonderful sixpennyworth.

The Contemporary Review.—The two most readable numbers in the *Contemporary* for this month are "Virgil in the Country," by the Countess Martinengo Cesaresco, an article redolent of the spirit of the Eclogues and Georgics, and Mrs. Fawcett's onslaught on Mr. Grant Allen and his "Woman Who Did." It is remorseless and extremely funny. There are, however, some grounds for Herminia being able to wait for her friend and compose her limbs after taking the poison. Death has been delayed after taking hydrocyanic acid for an hour and a quarter.¹ But Mr. Grant Allen's science is always a fine, free, careless rapture. He makes, in one of his earlier works, rattle-snakes come from India, and bacilli cultivations flourish best in the sunlight; but, then, a novelist, we suppose, may soar superior to natural law.

The New Science Review. April, 1895. London: Messrs. Gay and Bird.—This is the fourth number of the first volume of this new "miscellany of modern thought and discovery." It contains an excellent choice of philosophic subjects contributed by well-known writers and authorities. To give an idea of the range, we may allude to the admirably lucid article of Professor Crookes on the Elements, in which he summarises the present position of knowledge as to the nature of an element. What is an element, he asks, and how and where are we to draw the line? To which the only reply at present is: There are different grades in the elemental hierarchy, and different groups of the rarer elements are cited as shading off so imperceptibly into each other that no definite boundary can be found. This is followed by a very interesting posthumous paper—Autobiographical Notes—by the late Professor Richard Procter; while the remaining pages are devoted to such varied subjects as Genius, by W. G. Jordan; Where the Steamboat was Born, by Maggie Symington; The Ether and its Functions, by G. Fraser Fitzgerald, F.R.S., of Trinity College, Dublin; Changes in Spoken English, by A. B. Kingsbury; Electric Power Transmission, by Lieutenant F. Jarvis Patten; Hands as Indicative of Character, by "Cheiro"; Railroad Facts and Figures, by Melville Phillips; Operation of the Vibratory Circuit, by John W. Keely; The Veil Withdrawn, compiled by Mrs. Bloomfield Moore; Are Physical and Spiritual Energy Identical? by Mrs. Mary Parmelee; The Continuity of Life, by "Ormond." The contribution by Evelyn J. Hardy on Scientific Irritability is worthy of notice at the present moment, since it deals in a very fair spirit with the Muir-Dewar-Olszewski controversy on the question of priority in regard to the liquefaction of gases. Evidently Professor Dewar has a strong champion in this authoress. The unsigned article on the Unity of Life which follows is based on the work of Mr. Strindberg, "a man of literature," who "resinous product of oxygen, hydrogen, and carbon." We are by no means convinced that this is so by the arguments claims to have discovered that sulphur is a compound and a set forth; and for some time we were puzzled to know what the writer meant by alluding to the "destiny" of sulphur being 1.97. Of course it should be "density," but it is a bad slip for a scientific journal. It is clear that the review teems with subjects of the liveliest interest to the general scientific reader, and the matters dealt with are clothed in language which should be easily "understood of the people," not to say the "dabbler."

¹ Guy's Hospital Reports, 1868, p. 259.

THE LANCET.

LONDON: SATURDAY, MAY 11, 1895.

THE paper from the pen of Professor JOHN B. MURPHY which appeared in THE LANCET of April 27th has no doubt been very widely read. It is certainly a most important contribution to the discussion of a subject which deservedly excites a widespread interest. The tables of cases therein recorded afford striking evidence of the enormous strides that the surgery of the alimentary canal has made within the past few years. We believe we are well within the fact in saying that never before has such a list of cases been recorded—cases in which the gravest difficulties have been surmounted, partly by the exhibition of care and manipulative dexterity on the part of the operators, partly by the careful observance of the necessary precautions of aseptic or antiseptic surgery, but largely by the employment of the suture button which bears Professor MURPHY'S name. Intestinal anastomosis is an entirely modern procedure, but it so perfectly fulfills the indications in so many morbid conditions that it has naturally excited much interest, and many attempts have been made to perfect its technique. For, admittedly, the operation is one beset with special difficulties. The cases demanding it are often in a desperate state when coming under the surgeon's care, and a prolonged operation has often been the final drop in such patients' cups of ill. It has also been shown that the shock caused by manipulation of the intestine is altogether more severe than that induced by similar manipulation of the parietal peritoneum. The surgeon is therefore called upon to operate upon a part which is not well disposed towards operative interference, and upon patients who are themselves the worst of subjects for any operation at all. But, on the other hand, surgeons have proved by painful experience that intestinal anastomosis can only be successful when executed with the utmost nicety and precision. Many a case has been lost by the yielding of a single stitch, or by failure to secure the most exact and perfect apposition of the parts. The intestine, too, is the home of a virulent infective pyogenic organism, the bacillus coli communis, and failure to secure a perfect result only too often means certain death from infective peritonitis. This by no means covers all the practical difficulties in intestinal anastomosis: there are difficulties in diagnosis, difficulties caused by adhesions or other pathological conditions, and difficulties due to the great depth at which the manipulations have sometimes to be carried out; but those we have placed first are the two striking and essential difficulties that are met with in nearly every case alike.

The great aim of the surgeon has been to shorten the operation and at the same time to obtain perfect accuracy of apposition of the parts to be united. SMYTH'S name will always be honourably connected with this department of surgery, for he was among the first to grasp the essential features of the problem and to introduce a mechanical

appliance to meet them. He was followed by many others, who devised various modifications of his well-known decalcified bone plates—rings of catgut, bands of rubber, decalcified bone bobbins, and so forth. Then came a certain reaction against all such mechanical aids, and improved methods of direct suture—particularly MAUNSELL'S—promised to yield more satisfactory results. Following this we had from America a yet more complicated mechanical contrivance—the Murphy button, and to-day it holds the field. As Professor MURPHY'S paper indicates, it has now been largely tried by a great number of surgeons, especially in America and Great Britain, but also on the Continent of Europe. The consensus of opinion seems to be that it admirably fulfils the two primary requirements: it greatly shortens the operation, and by its use intestinal anastomosis can be made with great precision, and as a result the mortality of these operations has been greatly reduced. Against this most satisfactory result two facts may be mentioned as a set off. In the first place, the button is a rather complicated and very delicate piece of mechanism; it requires to be made very well, and to be used with gentleness and care. Again, the button, when set free by the separation of the rings of bowel compressed between the two portions of it, may linger for a very long time in the alimentary canal; but, so far, experience has shown that this retention of the button is not attended with danger. Too much weight must not be given to these objections to the use of the button. Simplicity of construction is to be diligently sought in all our appliances, and we doubt not that Professor MURPHY himself, or some other surgeon with a mechanical genius, will be able to devise some simple method of attaining the same mechanical result. Delicacy of mechanism is not a fatal objection, at most it is a remediable defect; and Professor MURPHY'S tables show that it is compatible with brilliant operative results. He has certainly succeeded in lifting this whole department of operative surgery—not one isolated operation merely—on to a different and better plane, and has given intestinal anastomosis a position in surgical therapeutics it has never held before. The paper by Mr. ERNEST LANE published in our columns last week, in which he recorded three cases in which he had used the Murphy button, fully supports our good opinion of this device, and he is able to add still more cases to those recorded by Professor MURPHY himself. No doubt the lists are by no means complete, and probably, as in most similar instances of a new operation or procedure, an undue proportion of successful cases have found their way into print. But this applies equally to all other methods of intestinal anastomosis, and in no way invalidates the comparison of the results of using the Murphy button with other modes of performing the operation.

One of Professor MURPHY'S "conclusions" is a very striking one, and if permanently borne out will be a most satisfactory one—namely, that the opening effected by his button does not become narrowed by the contraction of the cicatrix. This result has often followed upon the employment of other methods, and a satisfactory explanation of the different result when the button is used is

not forthcoming. In the meantime every care must be taken to test this statement, and if further experience fully bears it out it will afford another justification for the wider use of these admirable buttons.

It may seem to some that the Budget speech of the Chancellor of the Exchequer has no interest for medical practitioners. But this is a narrow view. Any such statement has direct interest for one of those professions whose quiet and modest incomes Mr. GOSCHEN was candid enough to confess were the object of his peculiar complacency and attention when he was in the office now held by Sir WILLIAM VERNON-HARCOURT. Even Sir W. VERNON-HARCOURT, who has been so anxious to extend the system of exemption to classes which can ill afford to be directly taxed, has not framed his exemptions to give any very practical relief to the large class of medical practitioners who are hardly worked and badly paid. But apart from the point that for another year at least we are doomed to pay the heavy demand of an income tax of eight pence, the Budget statement bristles with features and facts which are full of interest to all thoughtful citizens and to the members of the medical profession. Not the least interesting part of Sir W. VERNON-HARCOURT's performance on the Budget night was his solemn warning to all parties and to the public that the limits of taxation had been well-nigh reached. It is common enough for Chancellors of the Exchequer to preach economy, but there was an air of solemnity about the way in which the present occupant of that office used the occasion. Whatever may be the exact meaning of his mysterious remark that that was probably the last time he would be able to speak with his present responsibility on the subject, it will be remembered as a call on his successors and on politicians generally to cultivate the excellent quality of economy. The facts that the public revenue is now about double what it was fifty years ago and that in the last two years something like six millions have been added to the expenditure may well make Chancellors of the Exchequer pause and payers of the taxes tremble. We cheerfully admit that we get value received in many ways for the money in better local government, in education, in sanitation, and in a more effective protection of our empire by land and sea; but Sir W. VERNON-HARCOURT's remark is true: "The limit of tolerable taxation has been nearly reached." We say this with only too much right. We pay taxes heavily out of incomes that are hardly earned and that are generally inadequate to support the dignity of a learned and laborious profession—and one, be it added, which takes but little from the public purse. Out of the prodigious expenditure of a hundred millions no member of our profession connected with the service of the State receives a salary that would reward a third-rate lawyer who serves his party as if it were his country. If we may not hope for the recognition and reward of labour that adds immensely to the welfare and happiness of the State, we may at any rate claim to keep statesmen to the memory of Sir W. VERNON-HARCOURT's words, that the limits of tolerable taxation have been reached.

The essential features of the Budget are simple and not unsatisfactory. The calculations of the permanent officials of the Inland Revenue Department for the past year have reached the perfection almost of astronomical ones, and reflect high credit on that body of officials. Here it is not unfitting to say that if our public servants multiply on every hand, and in some departments receive salaries that appear large when compared with the more precarious incomes of private individuals, we are well rewarded in the character and capability of the men that guide successive generations of statesmen. The requirements of the Governments have been more than met, and a surplus of £766,000 realised and appropriated to a sinking fund. Every evidence of the substantial comfort and competence of the great body of the people was given by the Chancellor of the Exchequer, notably in the increased consumption of tea, of tobacco, and of cocoa; and in the increase of deposits in savings banks and in other ways, so that the accumulated savings of the humbler classes now amount to the enormous sum of £240,000,000. Mr. GIFFEN's great authority was quoted by the Chancellor to show that the year 1894, when all comfortable people were more or less forced to practise economy, was the most prosperous year the working classes have ever had. A striking proof of this was given in the fact that, whereas in the prosperous year 1890 the increase in the deposits of the savings banks was less than £1,000,000, in 1894 it was £7,000,000. Another proof scarcely less striking of the well-doing of the people is found in the increased consumption of meat, which has grown from 101.4 lb. in 1887-89 to 121.8 lb. per head in 1891-93. Of course, the real improvement of the people is not determined merely by the amount of tea they consume or even of meat; but there are indications, together with the accumulating savings, of real progress, of comfort, and of thrift, which cannot but be regarded with pleasure and which mere pessimists should lay to heart. The receipts of the Treasury having been so satisfactory it would have been unnecessary to impose any new taxation but for the fact that the extra spirit and beer duties lapse in July next and if not renewed would leave for the coming year a deficit of £319,000. To meet this the Chancellor had to choose between renewing the extra duty on spirits or the extra duty on beer. He entered into no disquisition on the relative merits of these drinks or their relative dangers, as might have been expected in one so keenly alive to the evils of the drink trade, but he decided to renew the tax on beer and not to renew the spirit duties. The choice has been criticised from various points of view and was associated with some possibilities of political and party advantage to which cynical politicians did not fail to ascribe a determining influence. However this may be, the choice was a questionable one from a medical and a moral standpoint. Both liquors are sure to be drunk in sufficiently large quantities, but the favour shown to spirits by one who boasts that he is a temperance reformer is curious. The new death duties have satisfied their author's expectations, though 75,000 persons who should have contributed to them have been unkind enough to live on. Evidently, rich men will have a greater

interest than ever in consulting their medical advisers, if for no other reason than the pleasure of disappointing the Chancellor of the Exchequer.

ALTHOUGH hospitals were not unknown before the Christian era—for we read of great monastic institutions during the spread of Buddhism in India 400 years before that era and of great public hospitals and schools of medicine, science, and law established in connexion with them by merciful Buddhist emperors—there can be no doubt that the development of hospitals and the succour of the sick and injured received an enormous impetus from the introduction of Christianity and the religious and moral principles it inculcated. During the plague in France there was a great addition to hospitals, and to isolation hospitals in particular, which were placed outside the towns; but institutions for the isolation of infectious diseases—fever hospitals—are a comparatively modern creation designed to meet the needs and requirements of our most modern systems of civilisation. They have now become quite a feature in the land, and many of them have been developed with an elaboration of care and comfort that leaves little to be desired. To indicate the extent to which this system has grown and developed of late years we may point to a voluminous Blue-book of 555 pages that has just been published and laid before the House of Commons regarding the accommodation for infectious diseases provided in sanitary districts of England and Wales. This volume gives a large amount of detailed information grouped together and tabulated in the form of a huge return, showing the area and population according to the last census of every urban and rural sanitary district, and also showing, as regards every such district and every port sanitary district in England and Wales, whether the sanitary authority had made special provision for the accommodation of cases of infectious disease, together with a large number of particulars as to the size of the population; the cost of the site and hospital buildings; the number of beds; the number of cases admitted and treated during each of the five years from 1888 to 1892 inclusive; and the annual cost of maintenance, as well as the arrangements for medical attendance, ambulance systems, and methods of disinfection in use. Before long this country will be covered with a network, as it were, of these institutions, varying in size and character according to the extent and nature of the different populations to be provided for. It becomes, therefore, a matter of vast importance to the community, on the grounds of efficiency and economy, that not only public health officers but the public generally should at any rate be acquainted with the objects in view of such hospitals and the general principles of their construction and working in view of their attainment. We all want to see efficiency, but it strikes us that with a rapid increase of expenditure every year, and the diminished incomes of the classes upon whom rates and taxes already press heavily and disproportionately, the question of finance is of increasing importance, and that architectural effect must altogether give way to what is really essential and necessary. Several excellent books and articles

have been published on the subject of hospitals for infectious disease, in addition to the Sanitary Act and the memoranda issued by the Local Government Board and the Metropolitan Asylums Board. But we desire now to call special attention to an article on Fever Hospitals by Mr. T. W. ALDWINCKLE and the discussion thereon published in the *Journal of British Architects* for February, 1895, in which our readers will find the question thoroughly debated and considered. Hospitals for infectious disease are divided into three kinds—viz., small isolation hospitals for villages or groups of villages, hospitals not exceeding 100 beds, and those for much larger numbers. The size, construction, cost per bed, and special features connected with numerous hospitals of this kind in this country and abroad are passed in review and illustrated by plans, and some points connected with the experience and practical results of various methods of administration and working are adverted to in their bearing upon the construction of ward blocks, ward offices, furniture and appliances, drainage, administration buildings, laundries, and numerous other matters more or less essential, or highly desirable, in institutions of this kind. The printed plans include some of the latest hospital constructions in the metropolitan area. The latest design is given of the large fever hospital projected by the Metropolitan Asylums Board, now in the course of erection—viz., the Brook Fever Hospital, Shooter's Hill—of which Mr. T. W. ALDWINCKLE is the architect. The plan seems to us very good and complete, and may be usefully consulted by those who are projecting or building hospitals of this character.

We had intended to go into the subject more fully than we have done in relation to several points of a more or less disputed or contentious character, such as the proper hygienic limits as to the size of a fever hospital, its site and distance from town, ground area, the provision or not of outside connecting corridors or covered ways, the width of wards in relation to their height, and other matters of the kind; but we find it impossible to discuss these within the limits of our present article. Our readers will, however, we feel sure, be grateful to us for directing their attention in the meantime to the paper on this subject in the above-mentioned journal.

Annotations.

"Ne quid nimis."

THE ROYAL SOCIETY.

AMONG the fifteen names selected by the Council of the Royal Society for election into the Society are those of three members of the medical profession: Dr. William Macewen, Regius Professor of Surgery of the University of Glasgow; Dr. Sidney Martin, Assistant Physician to University College Hospital; and Mr. W. H. Power of the Medical Department of the Local Government Board. We feel sure that this selection will meet with general approval, each of these gentlemen being fully worthy of the blue riband by achievements in different departments of medical science. Professor Macewen's fame as an exponent of cerebral surgery and a pioneer in that and other branches of surgical science and art is too well known to need

recapitulation. Dr. Sidney Martin holds a foremost position as an experimental pathologist and physiologist; his researches upon anthrax, diphtheria, and tuberculosis, which have considerably extended our knowledge of some of the deepest problems, have given him a position in the foremost rank of investigators. It is work of this class, strictly original and scientific, which the Royal Society does well to honour. Mr. W. H. Power has also fully earned the distinction of being admitted into the ranks of the Society. His contributions to epidemiology, undertaken during his long period of service at the Local Government Board, have been throughout marked by the scientific spirit. They are too numerous to mention in detail, but it is certain that no discussion of the etiology of such diseases as diphtheria, enteric fever, scarlet fever, or small-pox can be complete without reference to his important and exhaustive studies of epidemics of these diseases.

"HYPNOTISM" EXPOSED?

A CERTAIN well-known *prestidigitateur* whilst performing a particular piece of sleight of hand used to tell his audience that he would take them into his confidence and explain to them the *modus operandi*. "There are several ways of doing it," he would say; "some do it one way and some another, but I have no objection to telling you—strictly in confidence, mind—that I do it the other way." This in effect was exactly what Mr. Dale told a private audience who assembled in the South London Music-hall on Saturday last to witness "a complete exposure of the supposed hypnotic trances." At the outset Mr. Dale said he was going to prove that he could do to his subjects in the waking state exactly what so-called hypnotists could do to their subjects while entranced. In response to a request that some medical men should closely watch the proceedings two gentlemen took up a position on the platform. Two subjects (male and female) were then introduced, who placed themselves upon improvised beds consisting of boards resting upon trestles and covered with some kind of drapery. A "professional hypnotist" then entranced the subjects, and their insensibility to pain was tested by thrusting a large darning-needle through the arm. They were then awakened, and Mr. Dale proceeded to thrust a needle through one of their arms, while one of the medical gentlemen did the same in the case of the other. Neither subject showed any evidence of feeling pain, and in the case of the lady there was no blood drawn, but in the case of the male subject a little blood showed itself. The "Professor" now came forward and triumphantly stated that he had proved his case—namely, that hypnotism was a sham. To this there were cries of, "You have proved nothing," and a running fire of questions and answers between the *dramatis personæ* and the audience was kept up for some time. The replies of the former were, however, very incoherent, and no direct answer could be got from either of the subjects as to whether in the first instance they were only shamming sleep or whether they were really hypnotised. The "hypnotic professor" stated that up till now he believed that the subjects were under his control, and even now to a certain extent he believed that to be the case. He expressed his surprise, however, at what he had seen. The lady stated that she was hypnotised "to a certain extent," and "to a certain extent" she knew what was passing around her, and that her hearing "was intensified." Many questions were put, but the now stereotyped answer "to an extent" or "to a certain extent" was all that could be elicited. A Mr. Marshall was now brought forward, and stated that he was one of the subjects entranced at a recent exhibition of this kind. The trance was only a sham, however. The medical men were here invited to run a needle through Marshall's lip, but they very

wisely declined to have anything to do with it. Mr. Dale then thrust a needle through the lower lip of the subject, others through either ear, and six needles were hammered into the top of the skull, the subject afterwards coming among the audience and conversing with them with the needles *in situ*. We can only express our strong disapproval of the exhibition, not only because we hear it is to be continued, but because it proved absolutely nothing and the cause of science was not in any way advanced. Granting the existence of the hypnotic state, about which there can be little doubt, no proof was adduced to show that the subjects on Saturday were not still under control, although apparently possessing their own consciousness. This is, however, a theory we are not inclined to accept, although some colour is lent to it by the fact that a gentleman in the audience who wished to apply some tests in this connexion was rudely told that no one but a medical man would be allowed to touch the subjects. The most probable explanation of the phenomena is one that did not seem to suggest itself to the audience, and even if it had we do not see how it could have been proved under the existing conditions. We refer to local anaesthesia, however induced. The explanation of the subjects themselves is that they are trained to bear pain. This, however, we doubt. Had the needle been applied to other parts of the body the subjects might have told a different tale. Those who are acquainted with sleight of hand well know how easy it is in many cases to make a person do exactly what you want him to do while he is under the belief that he is doing exactly the opposite, and this struck us particularly while the arm was being offered and the needle presented for insertion. Exhibitions of insensibility to pain in the waking state are by no means new, for we remember that a year or so ago there was a performer in London who belonged or claimed to belong to the sect of the *Aissoua*. This man, after going through sundry incantations, stuck needles through his arms, a skewer through his tongue, and another under the skin of the abdomen without showing any signs of pain. Such exhibitions are as degrading as they are senseless, and the only possible object they can serve is to make prominent the morbid taste of the public who witness them.

ALLEGED SUICIDE BY STRYCHNIA POISONING.

IF we are correctly informed of the facts we do not hesitate to say that the proceedings at an inquest recently held in Yorkshire were very unusual. It is alleged that the wife of an innkeeper took the greater part of a "mouse powder" containing two and a half grains of strychnia. From the report furnished to us the only direct evidence on the point consisted of an admission of the deceased woman to her servant, emphasised as it was by a request that the maid should procure some linen wherewith "to lay her out, as she had taken poison." The powder is said to have been taken at 11.30 A.M. An injection of apomorphia given at 1 P.M. acted freely. At 2.30 P.M. there were no symptoms of poisoning, but shortly afterwards "characteristic spasms" were observed. The spasms gave way to morphia and chloroform inhalation at 8 P.M. The deceased was comfortable at 11 P.M. and also at 8 A.M. on the following day. Death occurred suddenly three hours and a half later. The deceased is said to have had frequent fits of heavy spirit drinking, and to have suffered at times from alarming cardiac failure. There seems little reason to doubt that strychnia was ingested, and that in a not inconsiderable measure it was accountable for the fatal issue, although the proximate cause of death was an attack of syncope, a not unlikely result of exhausting spasm in a person with the aforesaid antecedents. No medical evidence was called, although it was suggested by the jury.

Eventually a verdict was returned that deceased died from poison taken by herself while in full possession of her senses, and in consequence her body had not the customary rites of Christian burial. Although there was a high degree of probability that poison was taken, there seems to us to have been wanting that corroborative testimony which should be forthcoming to warrant a verdict of *felo de se*, and notably in the case of one addicted to alcoholic intemperance. Moreover, the deceased is said to have had some words with her husband because he remonstrated with her on the ground of her "besetting sin." If such was the fact, what is more likely than that she took the poison in an outburst of passion, her mind taking no cognisance of "right and wrong," and thus leaving her unanswerable for the act and irresponsible for the crime of wilful suicide? Although three medical men saw her during her last illness not one was called to testify (1) that poison had been taken, (2) that death resulted from poison, and (3) as to the mental condition of deceased. Fortunately, nowadays coroners' juries are lenient in their findings as regards the responsibility of suicides, holding the charitable view in the absence of strong proof to the contrary that the very act of self-effacement is in itself sufficient testimony of "temporary insanity." Such a procedure not only leaves the memory of the deceased free from the stain of an offence forbidden by God and man, but inflicts the least painful consequences on surviving relatives and friends.

THE CHITRAL EXPEDITION.

We do not think that people in this country and India were altogether prepared for the exhibition of promptitude in mobilisation and the skill, daring, and gallantry with which the Chitral expedition has been designed and executed by our European and native forces. We are so accustomed to decry our own military systems, and to dwell upon our unpreparedness and defects and draw an unfavourable contrast between ourselves and Continental Powers in these respects, that the spirit and boldness with which the Chitral affair has been conducted have compelled our admiration, and have not been altogether unmixed with pleasurable surprise. The material composing our British and Indian armies is splendid, and the fine qualities of our soldiers have never been better exhibited than on the present occasion. The physical and topographical difficulties were immense, and the enterprising work of the sappers in constructing bridges and works of a similar kind has been very hard. The marches undertaken by the troops have been long and very arduous. The special correspondent of the *Standard* tells us that a company of the Gordon Highlanders undertook a double march of twenty-six miles over a very bad road, and did it in ten hours, arriving in excellent form and spirits, ready to fight, if necessary, at the end of it. The force that left Nowshera have been bivouacking during the whole of the campaign with 16 lb. of kit for the men and 40 lb. for the officers. "How little," the correspondent adds, "this is you only find out when you come to try to get on with it." The men, he goes on to say, have nothing but two blankets, a waterproof sheet, a pair of socks, and a shirt. They form little parties of three; with two sheets supported by sticks they make a *tent d'abri*, placing the third upon the ground to sleep upon. Officers have commonly furnished themselves with small waterproof tents, weighing about 12 lb., and with some bedding, a change of clothes, and possibly a book they find that the allowed 40 lb. of baggage are soon reached. The weather is fine and the force is wonderfully cheerful and healthy. Considering the climate at this season, the rivers, valleys, and passes that have to be crossed, the extreme diurnal variations of temperature and those of different altitudes, the fortitude and endurance of the troops with their small amount of field kit are remarkable. But the

Indian forces are more or less accustomed and inured to this sort of thing, and hardships which in expeditions nearer home would be made much of are there taken as a matter of course and as incidental to campaigning in a mountainous country. The progress which has been made by the Indian Government in its military department since the last Afghan war in army reorganisation and field service is marked. It is gratifying to hear that the good work performed by the medical services has been generally recognised, and still more so that the great merits of Surgeon-Major Robertson and the conspicuous gallantry and devotion of Surgeon-Captain Whitchurch are thoroughly appreciated by all those who had the best opportunities of knowing what they have been.

A TRIBUTE TO SANITARY SCIENCE.

It is not often that ratepayers or their representatives are willing to admit that any benefits accrue from the expenditure of money on sanitary matters. When such testimony does occur, it is well to place it on record, so that others may follow the example. At the annual meeting of the ratepayers to transact business in reference to the Wigan Burial Board it was shown by the return of the clerk to the Board that the interments for 1894-95 had decreased by 236, and Mr. Councillor Ashton, in moving that the accounts be passed, is reported to have said: "He was gratified at the reduction in the number of interments, and he was sure the Sanitary Committee would feel that the money spent on sanitary matters had not been expended in vain. People grumbled at the money spent on sanitary improvements, but it spoke well for those improvements when, considering that the population was going up and they had passed through such a severe winter, there was a decrease in the number of burials."

THE COOKERY AND FOOD EXHIBITION.

THE eighth Universal Cookery and Food Exhibition, which was opened at the Portman Rooms, Baker-street, London, on Tuesday, May 7th, by Prince Edward of Saxe-Weimar, K.C.B., shows a marked improvement both in extent and quality on the previous exhibitions held under the auspices of the Universal Cookery and Food Association. As his Highness pointed out, the art of cookery is one upon which the health and comfort of the people depend, but we fear the attention which its importance merits is not accorded to the art in England. Indeed, as the Chairman, Mr. J. B. Buckmaster, said, if there is one art which has been neglected in the education of the people, especially among women, it is the proper management of the house, and this, of course, includes the proper preparation of food. He also gives it as his opinion that there is no place in the world where good food can be obtained so cheaply as in London, but this advantage is often lost for want of knowledge. In every household, whether rich or poor, the preparation of food is a necessity, and in proportion as this is done on hygienic principles will the health of the people be benefited. The object of the present exhibition, like that of its predecessors, is to spread a knowledge of the various substances used as food and to teach the best and most economical methods of preparing them for the table. Every kind of cooking, from that suited to the elementary school-girl of ten years of age to the most refined and artistic productions demanded by the epicure, is to be found among the exhibits; and practical object lessons and theoretical lectures are given each day of the week during which the exhibition remains open. Cookery for invalids and artisans is well represented, and the illustration of the new and improved system of cookery as introduced into the army should prove useful to all interested in the preparation of food on the most economical scale. In this

system prominence is given to the proper use of the stock-pot and the dripping-pan, two important processes in the preparation of cheap dishes, but the former is almost unknown amongst the poor, at any rate in England, and the latter, although represented by the frying-pan, is not at all understood. The economy of the system is easily demonstrated by the fact that three good meals per diem can be supplied for less than ninepence. To-day (Friday) the exhibition will close, and from one to three o'clock there will be a demonstration of army cooking and high-class cooking competitions, besides other attractions of a similar kind. Apart from its benevolent object in attempting to improve the domestic life of the people, the exhibition is well worthy of support, as the proceeds will be devoted to providing free dinners for poor children. On previous occasions various hospitals and benevolent institutions have benefited.

MEDICAL TESTIMONY BY A MIDWIFE.

IN another part of our present issue we draw attention to an inquest in which, in our opinion, medical evidence should have been called. On April 30th the county coroner held an inquiry at the Alexandra Hotel, Moss Side, into the cause of death of a male infant whose body was found in an ash-pit. A contemporary reports that the body was examined by a midwife, who was of opinion that the infant had not breathed after it was born; and it seems that upon this evidence the jury returned a verdict of "stillbirth," since there is no mention in the report that a medical man was consulted. We can imagine no other case where it is more necessary that the most competent opinion should be taken as to the cause of death, not only to establish the fact, but in view of a possible criminal charge, whether it be of concealment of birth or the graver offence of murder. The verdict of the coroner's jury in this case practically amounts to a bar against further inquiry, since it embodied the statement that the infant had not breathed after it was born. We trust that our information is incorrect or at least partial, for otherwise we cannot avoid the conclusion that a miscarriage of justice may have obtained.

A NOTIFICATION PROSECUTION.

ALTHOUGH dual notification is by no means a dead letter it is not at the present time carried out in the spirit contemplated by the Act. From time to time, however, instances arise which forcibly illustrate the importance of insisting on notification by the head of the family or nearest relative in cases where there is no medical man in attendance; and proceedings which have just been brought by the Aston Urban District Council against a householder for failure to notify is a good case in point. In this instance it seems doubtful if the defendant would ever have been brought to justice had not a notification been received at Aston from the medical officer of health of Brighton to the effect that a man, formerly a lodger in the defendant's house, had developed small-pox at Brighton. The defendant's wife, upon being interviewed by the deputy medical officer of health of Aston, stated that she let apartments and carried on a confectionery and milk-selling business. This woman further admitted that she had had a rash on her own body and that her daughter, aged seventeen, had had small-pox. The disease, she said, had not been notified owing to the damage which it was anticipated might thereby accrue to the business; her daughter, it appears, had been housed in an attic during her attack. This certainly seems a very gross case, and no plea of ignorance of the nature of the disease or responsibilities under the Notification Act was urged. It is indeed a matter of congratulation that in spite of the sale of confectionery and milk being continued no extension of the disease took place, and a fine of £1 and

costs seems a very lenient penalty for the negligence of the defendant in failing to notify. There also appears to have been in this case serious neglect on the part of the defendant in not calling in medical assistance. The report which has reached us does not enter into all the details, but doubtless Mr. H. May, the medical officer of health of Aston will furnish a full account of it in his next annual report.

UNIVERSITY OF LONDON.

A MEETING of Convocation will be held at the University Building in Burlington-gardens, on Tuesday next, at 5 P.M., when Mr. Bompas will move that the resolutions of Jan. 22nd, which affirmed the principle of one university for London and the reconstruction of the existing University, be rescinded. The decisions of the graduates will no doubt be largely influenced by the Bill which was introduced by Lord Playfair on behalf of the Government into the House of Lords on Thursday last.

SIR JOHN SIMON AND THE GENERAL MEDICAL COUNCIL.

WE regret to have to confirm the rumours that Sir John Simon has felt bound to resign his seat as one of the Crown members of the General Medical Council. Such a step has been only too likely for some time past. For one or two sessions Sir John Simon has been able to attend only with difficulty and with considerable effort and inconvenience. No member will be more missed than he, his judgment and authority in the class of questions which come before the Council being recognised on all sides. Sir John Simon may comfort himself with the reflection that he leaves his mark on such subjects, whether affecting the education or the discipline of the profession.

AN APPEAL FOR A MEDICAL MISSIONARY.

THE Archbishop of Canterbury's mission to the Assyrian Christians is in sore need of a medical missionary. The headquarters of the mission are at Urmi in Persia, but there is also a station at Qadshania, in the Kurdistan Mountains in Turkey. Any medical man willing to accept the post should be unmarried, for the life is somewhat rough. He will have expenses for his journey's outfit paid and will receive £25 a year. Board and lodging are provided free. In addition to this the Guild of St. Luke offers £100 a year. The practice would comprise ordinary medicine and surgery, a good deal of eye work, and sundry local fevers, together with occasional military surgery from chance encounters with Kurds. The climate is pleasant and healthy, horses are cheap, and food is good.

THE REGISTRATION OF MILKMEN.

THE control of the milk traffic is a subject which is daily receiving more and more attention at the hands of the public, and the recent report of the Royal Commission on Tuberculosis, more especially that part of it referring to circumstances determining danger from milk, will, we imagine, tend materially to the more rigid inspection of milch cows, to consideration of the conditions under which these animals are housed, and to the withdrawal from dairies of any cows with diseased udders. It will too, we trust, lead to a better observance of the Dairies, Cowsheds, and Milkshops Order, and to a more general adoption of the Infectious Disease Prevention Act in the provinces. As far as the metropolis itself is concerned, we note in the above connexion that the Metropolitan Dairymen's Society has submitted a proposal for the consideration of the London County Council that "it be provided that every person who vends milk in the streets or delivers the same at any house shall be required to wear a

metal badge denoting the licensed dairy from which the milk is supplied, and that all cans and receptacles used for the purpose of the trade for the conveyance or sale of skim or separated milk shall be clearly labeled to this effect with inch letters in brass on the can or receptacle, or on a canvas label attached thereto." It would certainly seem that some such identification as is here indicated would have the effect of enabling milk purchased in the street to be traced with greater facility than at present—that is to say, if the milk purchasers would take the trouble to observe the badge; and it might also afford to the public a better means of obtaining that for which they ask and pay.

THE OPIUM COMMISSION.

SIR JOSEPH PEASE is evidently not satisfied with the results which have been arrived at by the Royal Commission and which are published in their report regarding the opium traffic, for he is about to move a resolution in the House of Commons on the subject on the 24th inst. He regards the system—and hopes, of course, to carry the House with him—by which the Indian opium revenue is raised as morally indefensible, and urges that the Indian Government should cease to grant licences for the cultivation of the poppy and sale of opium except for strictly medical purposes, and that the Government should prevent the transit of Malwa opium through British territory. Our readers will find in the *Times* of the 7th inst. an article on Indian Affairs which is mainly devoted to the subject of opium and the results of the late investigation by the Royal Commission. Reference is made to the able communications which appeared in that journal in 1881–82 from Sir George Birdwood on the physiological aspect of the question and the ascertained effects of opium as used in India on the brain, the body generally, on moral character, and also on crime returns. The results were based upon the intelligent observation and experience of an impartially-minded authority; and the Royal Commission, after examining 700 witnesses and thoroughly considering the matter, has confirmed Sir George Birdwood's observations. The weight of evidence—that of medical men, missionaries, natives of India, and officials—was such as to have carried conviction to the minds of the Commissioners, as it has probably to those of most unbiased people. We shall, nevertheless, await the course and result of the discussion of Sir Joseph Pease's resolution with some interest and curiosity, if only to see what fresh evidence the anti-opium party can adduce.

THE ABERNETHIAN SOCIETY.

THE centenary of this society was celebrated by a conversation in the Great Hall and Medical School of St. Bartholomew's Hospital on the evening of May 1st, and was attended by a large number of members of the staff, lecturers, and past and present students. There were also present some well-known members of the staffs of other hospitals. The Presidents, Dr. Maddow and Mr. E. W. Cross, received the visitors in the Great Hall, in which there was an exhibition of letters, instruments, and other objects of interest in connexion with Mr. Abernethy lent for the occasion by Mr. Alfred Willett, Dr. A. Davis, Mr. Jeaffreson, and others. In this hall there was also an exhibition of New Zealand weapons &c. lent by Mr. James Berry and Mr. J. S. Mackintosh. At 9 P.M. Dr. Norman Moore gave a lecture on the History of the Abernethian Society, and at 10 P.M. Dr. Kanthack gave a lantern demonstration of Photo-micrographs of Bacteria. Drs. Ekins, Bowman, Klein, Fletcher, and Jones, and others exhibited microscopical sections and other objects of interest in the lecture theatres and laboratories, and there were surgical instruments by various makers on view in the anatomical demonstration room, where microscopes and ambulance appliances were also shown. Dr. Lewis Jones

showed a series of vacuum tube experiments to illustrate the phosphorescence of many bodies under the action of the electric spark, and also an apparatus giving high-frequency discharges at high potentials to show the striking effects first brought forward by Tesla and by d'Arsonval, such as the illumination of vacuum tubes without electrodes, and the glowing of bulbs held in the experimenter's hand or in proximity to the apparatus. Visitors also had the opportunity of testing for themselves the small physiological effect of the discharges of the high-frequency coil by closing the circuit through their arms, and of seeing the remarkable experiment of an incandescent lamp glowing brightly between the hands of two persons whose bodies conveyed the current supplying the lamp without feeling any painful effects. The members of the St. Bartholomew's Hospital Musical Society sang glees in the Library, and were followed by the members of the Dramatic Club of the hospital, who played the farce "A Regular Fix." The committee are to be congratulated on the results of their efforts to make this centenary a success.

THE USE OF ALCOHOL IN HOSPITALS.

DR. GAIRDNER'S influence in the abatement of indiscreet alcoholic stimulation in disease is well known, dating from his classical paper published in THE LANCET of March 12th, 1864, to which—as we remember with pleasure—we endeavoured to do sympathetic justice in THE LANCET of March 26th of the same year. Dr. Gairdner's article referred chiefly to the use of alcohol in typhus fever, of which he had quite an exceptional experience in the Glasgow Fever Hospital. Dr. Gairdner is evidently still interested in this great question. The *Glasgow Herald* of May 7th contains a letter from him commenting on a leading article in that journal of the preceding day on the consumption of alcohol in workhouses, which was based on a recent report to the Home Office. The interest of Dr. Gairdner's letter lies in its reference to the medical use of alcohol in a general infirmary of the first class—the Western Infirmary of Glasgow, of which Dr. Gairdner is one of the physicians. Doubt and disappointment are sometimes expressed by those who have the means of seeing much of the drunkenness of Scotland. But whatever the case as to the social and personal use of alcohol the following figures show that in the treatment of grave general disease, as seen in the Western Infirmary, its use is very limited indeed. The infirmary contains 400 beds. The following facts as to last year's bill for alcohol have been supplied to Dr. Gairdner by the superintendent: Port wine, £12; claret, 18s. 6d.; champagne, £8 9s. 0d.; brandy, £38 12s. 0d.; whisky, £61 4s. 0d.; gin, £1 14s. 0d.; malt liquors, £14 16s. 0d.: total, £137 13s. 6d. We need scarcely say that there is no interference—as these facts show—with the full discretion of the medical staff in the use of this medicine, any more than in the use of others. There can be little doubt that in all hospitals great care in the use of alcohol is shown. Dr. Gairdner's letter and facts will tend to confirm this.

IS AN ARMY SURGEON A MILITARY OFFICER?

MOST people probably would say that such a question was superfluous—that a gentleman holding Her Majesty's commission in the army must necessarily be a military officer; but apparently His Royal Highness the Commander-in-Chief is of another mind in the matter. When returning thanks for the Army at the Royal Academy banquet the Duke of Cambridge is reported to have said: "Your President has told us the men of the army are made of the same stuff as their predecessors. In proof of this I have only to refer to the gallant conduct of those distinguished officers Sir Robert Low and Colonel Kelly, and of that brave civilian Dr. Robertson.

(Cheers.)" Had this invidious distinction proceeded from almost any other quarter we should willingly have passed it by unnoticed; but coming from the source it does we can only enter a protest as warm as our respect for the well-nigh life-long services of the Commander-in-Chief will admit. Surgeon-Major Robertson is no more a civilian than are General Low and Colonel Kelly, or for that matter the Commander-in-Chief himself. We should have thought that the occasion afforded a singularly fitting opportunity for the utterance of a few well-chosen encomiums by the chief officer in the British army; but such well-deserved encouragement is too often conspicuous by its absence from any speech of His Royal Highness when the good services of military surgeons are in question. We are perfectly well aware that Surgeon-Major Robertson was employed at Chitral in a so-called civil capacity—we have yet to learn that his position deprived him of his rank as a military officer.

DIPHTHERIA IN LONDON.

FATAL diphtheria in London still maintains itself at what seems likely to be a normal height, the deaths registered in the last two weeks being respectively 27 (2 below the corrected average for the preceding ten similar weeks) and 29 (corresponding to that average). During the four weeks of three successive months the deaths have been: in February, 121; in March, 116; and in April, 107; a continuous improvement it is true, but not of any striking character. The notifications in the four weeks ended April 27th were 562 in the whole metropolis, only reaching and exceeding 10 in two sanitary areas, the case mortality being just a fraction under 20 per cent.; while in the succeeding fortnight the 300 notifications and 56 deaths yield a per case mortality of just below 19 per cent. Thus, diphtheria would not appear to be decreasing in actual amount, even if it be not quite so fatal. Of the 300 notified attacks mentioned, only 149 were removed to hospital; and the numbers of patients remaining under isolation have in the last four weeks been respectively 435, 441, 432, and last Saturday 457. Of the 56 deaths in the last fortnight, 41 were in children aged between one and five years. In this same period there were 23 deaths registered in Greater London, including 9 in West Ham and 4 in Edmonton districts.

THE TREATMENT OF PUBLIC DRUNKENNESS.

THE drunk and incapable are at all times more or less indebted to the attentions of the police, but for whose timely help fate would sometimes deal hardly with the semiconscious toper. In the modes of its expression, however, this care is liable to somewhat striking variations. Among ourselves there is apt to be too little regard for ceremony or even for necessary precaution. Elsewhere the error in judgment pursues an opposite course. A contemporary reminds us of the Danish method. This appears to be regulated by the principle of like to like, and accordingly treats the drunken in an almost indulgent manner and the sober with some rigour. The inebriate journeys in a cab to the police station, is there detained, and again driven home when free from the effects of drink. Cabman, constable, and surgeon have all in the meantime to exert themselves for the poor sot, and the bill of their united charges is presented to the publican whom he last visited. It is easy to see that errors and fallacies may readily arise out of this system, in which method surely is overdone, and the penalties of indulgence are exceeded by the labours of commiseration. A simpler plan should serve all useful purposes. The necessary points of procedure in such cases, we consider, should consist of a preliminary examination on the spot by the constable on duty, who must have some know-

ledge of ambulance work, this primary survey to be supplemented in cases of doubt or difficulty by a regular examination by the police-surgeon. Particular care should be taken to prevent avoidable exposure in the police cell, and in this direction there is still room for improvement. The charge made upon the publican, though no doubt liable more or less to misapplication, is not necessarily an unjust one. Two persons must concur in the offence of drunkenness; one who commits it and suffers by it and yet makes no amends, and another who aids and abets and is enriched by him. Both parties in our opinion owe some compensation to social decency.

NATIONAL SCHOOL CLOAK-ROOMS AS INCUBATION CHAMBERS.

A NEW YORK medical man has, it appears, been expressing his opinion that the outer clothing of public school children is one of the most active sources of the spread of infectious disease, and although his remarks apply in the first instance to America they are not without application to our own country. It is pointed out that the hanging up of wet and dry clothing, some of which may have come from infected houses, in juxtaposition in ill-ventilated and crowded cloak-rooms is a proceeding which lends itself to the growth and multiplication of micro-organisms. We are told that in America the clothing is sometimes hung in the school-room itself, and that the "wardrobe-room," where the outer clothing is usually deposited, is at times utilised as an extra recitation-room. The suggestion is made that the cloak-room should be thoroughly ventilated—and, we would add, well lighted—and that arrangements should be made for drying the children's clothes in wet weather. Without entirely subscribing to the sentiments above expressed, it must be admitted that considerable improvement might be made in our own country in the matter of cloak-room accommodation, and that, as far as possible, the clothing of each child should be free from immediate contact with that of others. The amount of outer clothing which the children of the poorer classes wear is frequently somewhat astonishing to persons differently brought up, and although the lengthy exposure, often in very inclement weather, which school attendance necessitates renders the careful clothing of children a subject of paramount importance, nevertheless it would seem to us that this object might often be attained with equal economy by fewer and better selected garments.

THE BELPER GUARDIANS AND ISOLATION.

AN interesting instance of the want of method and accommodation for dealing with infectious disease which still obtains in some districts has lately been witnessed in the Belper Union of Derbyshire. A case of small-pox occurred in the Alfreton urban sanitary district, which is situated in the union in question, and the patient, being attended by the district medical officer, was sent by him to the workhouse infirmary and conveyed there in an open cart by the sanitary inspector to the Alfreton Urban Council. On arrival the patient was isolated in the tramp wards, which were, it appears, converted into a temporary small-pox hospital. The Belper guardians are in a state of real indignation at a patient being brought from "one sanitary district to another," and they have passed a resolution that "the master have most imperative orders not to admit into the workhouse any person suffering from any dangerous or infectious disease and that notice be sent to the clerk of each urban district council in the union." The clerk to the guardians refused to express an opinion as to the legal aspect of the position when asked whether they had a right to refuse admission to those people whom one of their officers sent in as destitute; nor was he able to enlighten the

guardians when a proposal was made to prosecute the persons responsible for moving the small-pox patient to the infirmary—he was unable to state against whom proceedings should be taken or whether such proceedings devolved upon the guardians or the rural district council. If this case is really going into the law courts we shall watch it with the keenest interest; but in the meantime it would be well, it seems to us, if both the Balper guardians and the rural district council were to take steps to provide themselves with proper isolation and ambulance accommodation, and to a large extent the same remarks are applicable, as far as we can judge, to the Alfreton Urban District Council and to other urban district councils in the same union. These exhibitions of unpreparedness are far from edifying, and the sooner the authorities concerned appreciate and act up to their responsibilities the better. We imagine that the Local Government Board will have something to say to the conversion of the tramp wards into a small-pox hospital.

THE REGISTRATION OF MIDWIVES.

A LETTER advocating this measure, and signed "Honour Morton," appears in the *Daily News*, protesting that the Bill is in no sense intended to create a new class of practitioners. Whatever is done in this matter should be done conformably with the principle that a lying-in woman is peculiarly a subject for medical care, and that any midwife attending her does so in a limited and subordinate sense.

THE DIFFUSION OF SMALL-POX.

SMALL-POX has not been quite so quiescent in London in the past two weeks as in recent weeks prior thereto, the notifications last week being 11 in number, with 14 in the previous week, these totalling to 25, against only 35 in the whole metropolis in the four preceding weeks. In no district of London in the period last named did the cases exceed 6, and reaching this number only in Holborn and Lambeth. St. Marylebone had but two notified attacks. Of the 25 notifications in the last fortnight, 20 have resulted in removal to hospital, where on Saturday last there remained 34 patients under treatment, as compared with 53 a month earlier. Only one death from small-pox has been registered in London during the last seven weeks, this occurring last week in a vaccinated person aged under twenty years and belonging to the Rotherhithe sanitary area. Near at hand Bedford has had renewed experience of small-pox in the past month, but only to the extent of three or four attacks. Birmingham happily has been entirely free for some weeks. A few cases are reported to have occurred in Nottingham, and ten attacks have been chronicled in Liverpool during April. Other towns of Lancashire from which reports have come of the appearance of small-pox are Manchester (with four cases in the last three weeks after the total disappearance of the disease for more than a quarter of a year), Bolton, and St. Helens. In Yorkshire there has been some anxiety caused at Mexborough owing to a small outbreak of the disease, four or five cases being under isolation in the hospital, such as it is, belonging to the urban district, the first to be attacked being a tramp who, with his wife and family, was found in a common lodging-house, and removed to the isolation ward. His wife and children have also been removed, and steps have been taken with a view to watching the inmates of the lodging-house who were in close association with the sufferer prior to the diagnosis of his malady. Another case is said to have come into the town from a lodging-house at Wath-upon-Dearne. In Dublin the small-pox epidemic still continues, though to a much slighter degree than in past months. Thus in the last three weeks of April the admissions

to hospital were only 42 in all, the discharges nearly as many, namely 40, and the patients remaining under treatment, including acute cases and convalescents, respectively 107, 106, and 95. Of the 4 deaths registered in the period 3 were those of vaccinated adults over twenty years of age, and 1 that of an unvaccinated individual aged over forty years.

THE HEALTH OF PROFESSOR HUXLEY.

WE have great pleasure in stating that Professor Huxley has made steady progress during the past week. His temperature has remained normal, and he is taking nourishment well. He is able to be out of bed for a short time every day now, and altogether the outlook is much more hopeful.

MEDICAL MISSIONS.

AS we have elsewhere pointed out hospitals were not unknown before the Christian era, and our present hospital system owes its origin to monastic ideas; but religion and medicine have not always gone hand-in-hand, although for the better development of both it is well that such should be the case. Within quite recent years the religious bodies have taken fresh interest in medicine as an aid to the propagation of the Gospel, and the cry for more medical missionaries was the keynote struck at the annual meeting of the Medical Missionary Association held last week at Exeter Hall. The society was founded in 1878 to extend information, to deepen interest, and to give a more continuous impetus in England to the medical mission movement. Its methods are quite undenominational, and it does not confine its work to foreign countries alone, but seeks to establish medical missions among the poorer population at home. During the past year a net gain of seventeen has been made to the number of medical missionaries, raising the number of those holding British qualifications to 202. We fully sympathise with the objects of the association, and as long as nothing is done to lower the dignity of the profession we wish it every success. But such an incident as that related by one of the speakers at the meeting—in which two coolies and a cook, after watching the methods of the missionary for a few weeks, set up a rival establishment for the cure of opium cases—is only too likely to bring the profession into ridicule; and although circumstances soon dissolved the partnership and broke up the establishment a little care might perhaps have prevented such a thing from happening.

THE LATE PROFESSOR CARL VOGT.

THE death of Carl Vogt (to whom further reference is made in our obituary column) has deprived Switzerland of one of her most illustrious children and science of one of her most devoted and laborious followers. Vogt was a naturalist in the same sense as Linnæus, a geologist as much as a zoologist, an intelligent traveller as much as a physiologist. He was a teacher not only of professorial classes, but of a wide circle of intelligent lovers of nature. In losing him we lose almost the last of the giants whose labours have resulted in the present condition of zoological knowledge. Vogt's first work of importance was his account of the Embryology of the Salmon, which he contributed to Louis Agassiz's "History of the Freshwater Fishes of Central Europe"; this was rapidly followed by his account of the midwife toad (*Alytes obstetricans*). Like Kölliker and van Beneden the elder, Vogt fell into the error of supposing that developmental history might by itself form the basis of a systematic arrangement of the animal kingdom; but, on the other hand, his division of "worms" into flat, round, and ringed worms is still in its essence accepted. Vogt was one of the first to recognise the annulate affinities of the leeches. He was one of the

pioneers in our knowledge of that curious modification of one of the arms of the male cuttlefishes and squids (*Cephalopoda*) which is known as hectocotylisation, while his contributions to vertebrate morphology were considerable. But although Vogt wrote in conjunction with E. Yung a widely used text-book of Zoology, he never lost his interest in the geology of the Alps or the early history of mankind; the modern science of microscopical petrography was another subject in which he took a deep practical interest. Of Vogt, as of Casanbon, we may say:

"O doctorum quicquid est
Assurgite hinc tam colendo nomini."

MR. F. HAYDON, L.R.C.P. Lond., assistant surgeon to the West London Ophthalmic Hospital and honorary secretary, has been elected Secretary to the Court of Examiners of the Society of Apothecaries, in the place of Dr. C. E. A. Semple, deceased.

We are asked to state that the festival dinner of the Royal Medical Benevolent College will be held on May 15th in the East Foyer Dining-room of the Imperial Institute, instead of at the Queen's Hall.

THE LANCET

Special Sanitary Commission

ON

THE VENTILATION OF HOSPITALS AND THE TREATMENT OF INFECTED AIR.

IN no other buildings is it more essential or vital that ventilation should be efficient and conducive to comfort and to health than in those set apart for the tending and nursing of the sick. Most of our large hospitals were founded at a time when methods of ventilation and sanitation were crude, but even in hospitals of comparatively modern construction, in which the sanitary arrangements may be perfect so far as regards the removal of effete liquid and solid products, there will generally be found much that can be done to improve the satisfactory displacement of vitiated air and the means of providing a fresh and pure supply. The importance of such a provision is doubly emphasised when we consider, as experience has shown, how beneficially the free and open atmosphere ministers to the healing of wounds and to the elimination of morbid conditions. No apology is needed, therefore, if we lay before our readers the details of so important a departure in regard to the construction of one of our large provincial hospitals as the installation of a new method of ventilation which, we venture to think, is far in advance of any scheme which has hitherto come under our observation, and more particularly because not only does it provide for the efficient and salutary ventilation of hospitals, but also for the treatment, if need be (by means of antiseptics), or purification of the vitiated air of the wards before it passes into the outer atmosphere. For the present, however, we will confine ourselves to the method from the point of view of ventilation only, and in a succeeding section we will describe how this system may, by the simplest, and, we think, most effective, manner be employed for the treatment of vitiated air with the important view of preventing the spread of infection from such buildings as small-pox and scarlet fever hospitals. For this purpose we cannot do better than take as an illustration the New General Hospital now in course of erection in Birmingham, which, by the courtesy of the architect, Mr. Wm. Henman, we have recently had an opportunity of inspecting. Let it be understood that in doing so we are not dealing with a system

that has merely been projected, but with one that has already been carried into practice in several infirmaries and other buildings, schools, police courts, and the like, and which, as we have just said, has actually been provided for in the plans of one of our great hospitals. The building operations, indeed, at the New General Hospital, Birmingham, are so far advanced as to afford a clear idea and plan of the installation which is to effect the ventilation of the hospital.

It will be well first to review briefly the systems of ventilation which are at our disposal. These are: (1) ventilation by aided means—so-called artificial ventilation, (*a*) extraction, (*b*) propulsion, (*c*) agitation; and (2) ventilation without these means—so-called natural ventilation. It should be observed that the expressions "artificial" and "natural" when applied to ventilation must only be regarded as convenient merely in distinguishing between induced and unaided ventilation. If we define ventilation as consisting in the supply of fresh pure air suitably tempered and humidified, and continuously introduced so as to prevent stagnation in any given space which has become vitiated or is liable to vitiation, in such a manner as to give the greatest comfort to those individuals who may be present, then obviously it is absurd to qualify it by either term. Ventilation is ventilation whatever may be the means employed. The means of attaining the end may, however, be correctly described as artificial or natural as the case may be. "Natural ventilation," which simply means the opening of windows and letting the air move about at will (it may be by propulsion or extraction, or the air may be quite stagnant, in which case little or no ventilation is effected), is obviously unsuited for a hospital, since it cannot be placed under control in regard to temperature and purity, especially in such a variable climate as ours, and in our towns where we have often to contend with a smoke-laden and otherwise impure atmosphere. We may pass, then, to the various means of inducing ventilation. Of these we may dismiss the agitation or punkah principle, which at its best simply stirs and mixes the air, but does absolutely nothing beyond making it of uniform impurity. This reduces us to the question as to which of the two systems—extraction or propulsion, based respectively on the vacuum and plenum principle—is the better adapted, more particularly for the ventilation of hospitals and similar buildings. After a very careful consideration of both systems we are led to the conclusion that the propulsion system offers very distinct and important advantages over the extraction system, which we shall shortly point out, and which in kind are of especial importance where the ventilation of places in which the treatment of the sick and diseased is concerned. This conclusion is forced upon us because, as we shall presently show, complete control may be had over the propulsion system, while the extraction process introduces some objectionable features which cannot apply to the former, and which would be difficult if not impossible to avoid. In the extraction process, for example, it is true that air is constantly being extracted and replaced by other air, but the source of this incoming air is unknown, since it may be drawn in from any possible crevice. Special inlets, however, may of course be provided, but then comes the difficulty of regulating the temperature and the purity of this incoming air—a matter of the utmost importance where the atmosphere is liable to the pollutions of a town and the effects of ever-varying climatic conditions. On the other hand the propulsion system is under complete control, the site from which the air is taken may be selected, the impurities of environment may therefore be prevented, the air can be purified, humidified, and warmed, while extraneous and it may be dangerous sources of ingress are completely avoided, the supplied air tending to leak outwards through any unseen or accidental crevice through which otherwise impure air may gain an entrance. Having thus pointed out broadly the advantages of the propulsion system, we may next describe it in detail, selecting as one illustrative method of its application the installation at the New General Hospital, Birmingham, while incidentally we may mention one or two examples of its application elsewhere.

At the outset it should be stated that the method of ventilation about to be described is primarily due to Mr. William Key, an engineer of Glasgow. In applying the Key scheme to a hospital, a selection is first made of a position, uncontaminated by surroundings (or of more than one such position if the buildings are extensive), where air can be drawn in towards an extended screen, kept moistened with water

and periodically flushed to free it from the large amount of dirt which it intercepts. The screen is formed of a series of cocoanut fibre cords stretched vertically and interlaced with copper wire to keep them in position. On the outer side a coil of steam or hot-water pipes is placed to prevent freezing in the winter, and on the inside are other heating coils, arranged so that by means of doors or louvres the air passing through or under them may be regulated. It is then forced onward by means of a rotary fan or air-propellor, set in motion by steam, water, gas, or other power—preferably an electric motor—and finds its way to the several rooms, wards, or corridors by means of a wide and lofty horizontal duct and up flues, all calculated to the required areas, at the base of which are more heating coils, together with a simple contrivance by which both the volume and temperature of the air supply to any separate part of the buildings can be adjusted to a nicety.

The air enters where required by means of trumpet-mouthed openings, at about two-thirds the height of the storey, so as to disperse evenly throughout the apartment; and at the same time it expels an equal amount of air, principally through openings provided on the same side of the room as the inlets, up flues of the proper sectional area, into ducts in the roof and thence to the open, through valved and louvred turrets or flaps, four-sided, so that outer movement of the atmosphere shall exert no adverse influence upon the outflow.

These outlet air valves are so constructed as to place the air within the building under a slight pressure of about four ounces per square foot in excess of the outside atmospheric pressure at the time. In the New General Hospital at Birmingham an installation has been provided for heating and ventilating the buildings, the cubical capacity of which equals about two million feet; so that, as the air may be changed ten times per hour without opening any windows, twenty million feet of air every hour has to be propelled, cleansed, and warmed; for which purpose there will be eight "fans," from 6 to 8 feet diameter, to be turned by electric motors, 2000 superficial feet of cleansing screen, and about 35,000 feet of steam tubing.

A word in regard to the screens, which form a very important feature in Mr. Key's method. As has already been partly indicated, this apparatus, which is designed for the filtration and washing of the air, consists of several thousand cords of suitable material, stretched from a beam near the ceiling to another near the floor of the air chamber. When finished, the screen has the appearance of coarse cloth stretched across the apartment. The cords are placed so closely that they touch each other, copper wires are laced through the vertical cords in horizontal rows, and, being drawn tight, give the screen a flat surface; the rough fibrous nature of the material breaks up the entering air into very minute streams, which pass through equally all over its surface. These screens may be formed double, in order to give an extra cleansing or scrubbing surface when so desired. The screen is kept moist by water trickling down each cord, and at regular intervals of more or less frequency an automatic flushing tank discharges a considerable volume of water down the screen, to remove loose matter which may have collected, and to thoroughly wet the whole surface. Its purifying effect upon the air is remarkable. It prevents, for instance, the entrance of fog into the wards, the clearness of the atmosphere within, in spite of a dense fog without, making it almost difficult to believe that the incoming air is not derived from any other source than that prevailing under the objectionable conditions outside. There is no doubt, in view of this result, that the greater part, if not all, of the dust particles of the air are also removed. The attraction which moistened surfaces possess for suspended particles is well known, and it is just this principle, in fact, which underlies the successful working of a Pasteur filter in removing micro-organisms from water. When fog is being dealt with it is curious that the air within appears brighter and clearer even than when there is no fog outside, so that doubtless the condensed particles of fog effect the deposition of much suspended matter usually present in the air. When the fog is very dense drops of water from the screen are in colour like drops of black ink, so that the removal of objectionable suspended impurities, which, if left to ventilation by natural means or to many methods of ventilation by extraction would pass into the wards untrapped, is not the least important function of the screen. In the same way it is exceedingly probable that micro-organisms would be arrested mainly by deposition upon

dust or moist particles, and a large reduction of their number effected.

It was the important purifying property of the screen just alluded to which led Mr. Wm. Henman to suggest that the outgoing air, after being vitiated or infected by patients, might again be purified, so far as regards infection by the use of similar screens at the outlets. This project is so important in connexion with the construction and site of infectious diseases hospitals as to merit very serious consideration and attention at the hands of the profession and others who are interested in the subject. Mr. Henman considers that in fever hospitals each block of buildings should be separately supplied with an air intake, screen, heating coils, and fan, which in a building of only one storey may be arranged in the roof space.

Mr. Henman takes no credit for the method by which a suitable supply of air is cleansed, tempered, humidified, and propelled into the buildings, but acknowledges his indebtedness to Mr. Key for the assistance he has rendered in working out his ideas in connexion with the methods he adopts. It is simply proposed that air, so cleansed, tempered, and humidified, should be propelled through narrow, wedge-shaped openings in the ceilings, and, by means of a simple form of spreader, evenly distributed throughout the wards and corridors.

The feature which Mr. Henman claims to be a novelty is the placing of a screen (somewhat similar to those employed by Mr. Key at the air intake) at the head of every bed, and keeping the same charged with a disinfecting fluid. An outlet flue will be provided at the back of each screen, so that as fresh air is constantly being propelled into the ward an equal quantity will be forced through the screens, all other outlets being stopped, consequently almost immediately the air becomes contaminated it will again be purified *even before it actually leaves the apartment*, and thus purified will pass up the flues and into the open air. A very simple contrivance is employed for keeping the screens constantly charged with disinfecting fluid, so as to obviate disturbance to the patients in the wards, and reduce personal attention to the least possible limits. The disinfecting fluid found to be perfectly effective in destroying disease germs is a weak solution of carbolic acid. Above and below each screen a shallow trough is placed, the upper and lower ones respectively being united by lead piping, carried to any convenient position outside the wards, each connected to a cistern of moderate dimensions to which a small pump is attached, so that as the fluid flows along the upper pipe and trickles down the screens the surplus is caught in the lower troughs and returns through the other pipe to the lower cistern, whence it is pumped to the upper one. This may be made practically automatic by applying to the pump the same motive power used for turning the fan which propels fresh air into the building, and by having a third cistern or reservoir with regulated supply to make up for loss of fluid by evaporation from the screens. There can be little doubt of the efficacy of the screens in removing micro-organisms in view of the indications afforded by a series of very searching and exhaustive experiments carried out under the direction of Dr. Sims Woodhead and Dr. Cartwright. The results of this investigation may be summoned up as follows:—

1. Micro-organisms are entrapped by passing air through moistened screens.
2. The apparatus employed in the experiments in which dust loaded with organisms was forced through an experimental screen into a wooden chamber from which samples of the air were taken from time to time for bacteriological analysis gave in all probability less perfect results than would occur in practice, because in these experiments the air, highly charged with micro-organisms, was both forced directly through the screens and also by force drawn through them, whereas in buildings the air would be propelled gently through the screens simply by the slight pressure of the incoming air, no suctional force whatever being employed.
3. The very marked diminution in the number of micro-organisms which passed through the screens when supported by means of perforated zinc, and the smaller number still which pass through a thin layer of cotton wool, indicate varying powers of filtration and point to the possibility of devising a screen which will practically free the air from germs and yet not unduly retard the expulsion of the air from the building.
4. In proportion to the closeness of texture of the screen material, the size of the screens must be increased so that the

air may pass through them with the least possible force being required to expel it.

5. The moistened screens are all that is required to *arrest* the germs, but carbolic acid should be added for *destroying* them.

6. Disease germs or fungi likely to be conveyed by the atmosphere are usually found attached to comparatively large floating particles, as the scales of the epidermis, or fluffy shreds of material which would be entrapped by the screens in greater proportion than the germs experimented with.

In accordance with the suggestion contained in paragraph 3 that better results might be expected by the use of finer screens yet of ample size to permit of the passage of air, a building has been erected in which these suggestions can be adopted, and tests will shortly be made exactly on the same lines as when the screens are employed for the purification of air emitted from hospitals. It is probable, again, that the passage of large volumes of warm air through the screens would volatilise a considerable quantity of the disinfecting fluid with which the screens will be constantly charged, and that any germs which might not be entrapped by the screens would thereby be quickly deprived of vitality, and, moreover, that the mere reduction of the number of germs would be a considerable safeguard, because the attenuation of germs, as is well known, lessens the severity of their effects.

As regards the cost of the method proposed, the necessary apparatus is stated to be quite inexpensive and easily applied, and Mr. Henman is prepared to show that buildings can be erected and equipped at considerably less cost than is now expended upon hospitals relying only upon the ordinary means for ventilation, without any appliance for purifying the air emitted. More space for the patients has been the demand for some time, which, beyond a given area known to be necessary for nursing purposes, in reality means more *air*. It is very naturally asked, where, with such a constant change of air, is the necessity for more space within the hospital than is required for tending the patients? It is contended that with suitable appliances by which the air can be constantly and quickly changed, as in Mr. Key's method of ventilation, buildings might be less in cubical capacity by at least one-third; and not only would this reduction in size more than compensate for the cost of apparatus and its working, but the daily labour and charges for heating, lighting, cleaning, administration, and maintenance would be proportionately less. Another point of importance is that those who tend the patients would be constantly in a pure atmosphere, for no sooner is the air vitiated by contact with the patients than it is at once purified and expelled.

To conclude and to recapitulate, the system of propulsion as just described seems to us to offer very distinct advantages which cannot possibly be claimed for other systems. In the first place, the source of the air-supply is known; then the air is not only cleansed of ordinary dust and dirt, but also freed from flies,¹ moths, and other insect life, in addition to which carefully conducted scientific experiments have proved that micro-organisms are entrapped by the moistened screens. Again, another important function of the screens is to maintain the air-supply in a proper state of humidity, for, odd as it may seem, they moisten the air when too dry, and dry it when it is over-saturated with moisture. Further, any suitable temperature can be maintained for an indefinite time in any apartment, and for each it can be regulated, and that without any open fires, with their attendant dirt, labour, and noise, in keeping up and in conveying coal about the buildings, and without a single steam or hot-water pipe in any habitable part of the same. Complete change of the air throughout the buildings up to ten, twelve, or even more times an hour without draughts, can be effected, and general cleanliness about the buildings be ensured, all incoming air being relieved of its impurities, and all repairs to apparatus

executed without the necessity of even entering any habitable parts. The absence of draughts is perhaps the most pleasing, as it is one of the most satisfactory features of Mr. Key's method. This is all the more remarkable when we consider how rapidly the air is being changed. Lastly, by carefully regulating the positions and areas of the incoming and outgoing flues respectively, each department has its air changed without reference to any other part of the building. We have seen the system in working order at the Aston Police-courts. The stuffy, stale, and unpleasant character of the air of such places during the hearing of cases is only too familiar, but since this method has been in operation the air of the courts has been entirely free from any reproach on each and all of these heads. As to cost, that is a question, of course, which the committee of the New General Hospital were bound to consider, but they were satisfied that the method would effect a great saving of labour. Thus, for example, there being no fireplaces, coal need not be carried about, dirt is avoided, and as there are neither steam nor hot-water heating pipes in any habitable part, there are no inaccessible places behind which dirt could accumulate. The air-supply is clean and the influx of dirt and dust by means of open windows is avoided. As to the ducts and flues, they are of large size, readily accessible, and provided with means for periodic cleansing.

Lastly, the proposal to deal with the infected air of hospitals with the view of ensuring an innocuous effluent of air into the outer atmosphere is perhaps the most interesting, if not important, aspect of the propulsion system. It has been shown that the mere interposition of moist screens eliminates the greater part of bacteria and fungi from the air, but the use of a liquid disinfectant for this purpose would probably not only effect the arrest of the germs, but also their extinction. The latter object has been attempted with variable success by means of heat. In this connexion Dr. Barry's report to the Medical Department of the Local Government Board on "Certain Methods in use for the Sterilisation of the Exit Air from the Wards of Small-pox Hospitals" is of interest. The following is a comment upon this report which appeared in these columns² under the heading of "The Cremation of Infected Air": "Attempts have been made of late to carry into practice the suggestion made some twelve years ago by Professor Burdon Sanderson that the risk of aerial convection of disease might be met by disinfecting the air passing from infectious wards by drawing the air along definite channels and sterilising it by exposure to heat. In the hospitals recently erected by the Nottingham, Barnsley, and Bradford corporations the architect in each case had sought by means of furnaces in the course of the outlet shaft to secure the double object of ventilation by extraction and the 'cremation' of the outgoing air. At Barnsley and Nottingham gas-furnaces were employed for the purpose, and air was admitted to the wards by windows and ordinary inlet-ventilators, while at Bradford extraction was effected by a powerful furnace to which the outlet flues were conducted, and special inlet flues were provided through which alone air was permitted to enter. In the two former places the results were in no sense satisfactory. The extraction was insufficient to prevent occasional outflow of air from the ward through openings meant to serve as inlets only, and the air, after passing the furnaces, was found to be by no means sterile, but, on the contrary, to contain microbes capable of cultivation on agar-gelatine. The draught, too, tended to extinguish the gas jets, and at the Nottingham Hospital bits of cotton-wool and tissue paper were carried through intact. At Bradford, again, the sterilisation proved to be incomplete, and, although the arrangement of inlets was such as to prevent any reversal of the current in them and leakage of infected air, Dr. Barry very properly takes exception to the precarious character of a system of ventilation which is dependent solely and absolutely upon uninterrupted efficiency of stoking. It is possible that better results may be obtained by the aid of propulsion, or mechanically forcing fresh air into the wards, an excellent example of which—at the Victoria Infirmary, Glasgow—is described in the appendix to the Memorandum; but it seems clear that up to the present time the attempts based upon extraction alone have been attended with such a very modified degree of success as to count as failures in practice."

¹ The necessity of a precautionary device of this kind in infectious diseases hospitals has recently been strikingly emphasised in a series of experiments made by Mr. W. T. Burgess. In these experiments flies were placed in momentary contact with a cultivation of *bacillus prodigiosus* (or other suitable chromogenic organism) and allowed to escape into a large room. After some time they were recaptured and caused to walk for a few seconds over slices of sterile potatoes, which were then incubated for a few days. The experiments showed that the flies' tracks on the potatoes were marked by vigorous growths of the chromogenic organism, even when the flies spent several hours in constant activity before they were recaptured. The use of pathogenic organisms in these experiments would of course be attended with obvious dangers, but the result obtained with harmless microbes indicate the constant risks to which flies may expose human beings. Vide THE LANCET, May 4th, 1895.

² THE LANCET, Sept. 8th, 1894.

The Key method of ventilation has met with very distinct success where it has already been installed, as, for instance, at the Victoria Infirmary, just mentioned, in several schools, and in other public buildings,³ and the results of its adaptation to a large general hospital such as that in course of erection in Birmingham will be watched with very great interest, the completion of this admirably designed building being expected in about two years' time. The practicability of the method, however, is obvious. The important proposal of the architect, Mr. Henman to disinfect the outgoing air of infected wards where the Key method of ventilation is in force has of course not yet been put to practical test, but there is good ground for believing, as we have already shown, that this important adjunct to Mr. Key's methods of applying the propulsion system of ventilation may offer a really satisfactory solution of that difficult question of how to make infectious diseases hospitals safe to the surrounding neighbourhood. At any rate, the method, with its proposed augmentation, is of sufficient importance and scientific merit to demand the careful and serious consideration of all those interested in the vital questions of the ventilation and the purification of the air emitted from infected buildings.

We congratulate the authorities at Birmingham on the trouble and care they are taking to provide and equip a hospital fully in accordance with the requirements of modern scientific research, and we trust that other communities which may be brought face to face with a similar problem will evince an equal share of anxiety to attain so admirable and worthy an end.

SANITARY INSPECTORS' ASSOCIATION.

ON May 3rd Sir Walter Foster received a deputation from the Sanitary Inspectors' Association, who laid before him their views as to the form in which the proposed Examination Board for granting certificates to sanitary inspectors should be constituted. There were present Sir Benjamin W. Richardson, Lord Chelmsford, Mr. Percy Thornton, M.P., Messrs. W. H. Alexander and W. W. West (Vice-Chairmen of the Sanitary Inspectors' Association), C. W. Raymond (treasurer), J. Young, R. Chamberlain, A. Grant, A. Chadde-ton, T. G. Dee, F. W. Strutt, C. T. Wilson, A. Taylor, T. Ashdown, W. H. Grigg, and Edward Tranmer (honorary secretary).

Sir B. W. RICHARDSON: This deputation is the outcome of a conversation that took place at the last meeting of our Association. We, as an association, are very anxious to get a good examining board; it is very essential to the inspectors themselves, as it would be a spur to action on their part in carrying on the sanitary improvement which has been so very marked of late years. The sanitary inspectors are very anxious concerning the status and respectability of their calling. They would like to follow the medical profession in respect of recognising no one who is not duly qualified. You are aware that some years ago when the Sanitary Institute was first established we started an examining board, of which I was a member, and this examining board has continued to hold examinations and grant certificates to sanitary inspectors up to the present time. I think in many respects the Sanitary Institute has done its duty in this matter very well. But it does not seem to us at all a satisfactory state of things that an outside body like the Sanitary Institute should have the monopoly of the power to grant such certificates; nor does its certificate seem to us a sufficient guarantee of qualification. Lastly, there has been a proposal that a sort of limited company should be formed, which company should be incorporated under the Companies Acts and have a hall of its own, something like the Apothecaries' Hall, and that this company should elect a body of examiners. But the Sanitary Inspectors' Association has come to the conclusion that the Local Government Board itself should elect an examining board. The Sanitary Institute would like men like yourself, who are acquainted with those best fitted to be examiners in such subjects, to select the most competent individuals to form

such a board. A board of examiners appointed by you would be perfectly independent of all interests: they would not be looking for fees, or be influenced by any society feelings or considerations, but would be thoroughgoing examiners. Then, again, they would not only be independent, but they would occupy a secure position. You will bear presently that the Board of Trade is doing precisely what could be done by the Local Government Board. This is the suggestion which we want to submit to you before anything is done. I think if it were acted upon it would not only be the most beneficial plan, but the action would be politically sound.

Mr. ALEXANDER: We ventured a short time ago to address you on the subject of the tenure of office of sanitary inspectors and the inadequacy of the salaries appertaining to those offices, matters in which we were deeply interested and which greatly affected the public welfare. But we now come to you on a matter of even greater importance, and one in which we believe the public to be even more concerned. No doubt, in the first instance, the examinations conducted by the Sanitary Institute were carried on with very great advantage to all concerned; but our attention was some time ago drawn to the fact that the examinations were not all we could desire, and we made repeated efforts to come to an understanding with the Sanitary Institute. We made certain advances to them with a view to rectifying what we considered was lacking in the examinations and what we considered might be done to make the examinations more useful. These advances were not met in the spirit we had hoped they would be, and, therefore, our position remains unchanged up to the present. We think sanitary inspectors are often appointed who are not qualified in the way we have a right to expect, and we are anxious to improve their status. We feel that we are justified in bringing under the notice of the Government the fact that a sound examination is absolutely necessary in the interests of public health. Since the Sanitary Institute started holding these examinations other large bodies have been formed and have become interested in this matter—e.g., our own association, the British Institute of Public Health, and the Institute of Medical Officers of Health. A sort of limited company, comprising representatives from all these, has been suggested to form an examination board. We are very strongly of opinion that no private enterprise will meet public requirements in this direction and that it is only by a sound examination undertaken by the Government that satisfactory results can be secured.

Mr. GRIGG (Fulham): We thought in bringing this matter before you that you were not very likely to be satisfied with our taking certain generalities for granted, and that we ought to be prepared with some detailed scheme. With that object I have made very careful inquiries into the methods of examination for candidates for various professional appointments—e.g., factory inspectors and Board of Trade inspectors of weights and measures. I have more especially studied the method of granting certificates by the Board of Trade to marine engineers. These marine engineers occupy positions of great responsibility as regards human life, and I think I need not say much to convince you, Sir, that we as sanitary inspectors also hold positions of equally great responsibility. I will ask you to allow me to point out the sections of the Merchant Shipping Act under which these examinations are carried out. Well, sir, we think that that is the sort of thing that is required for us. We think an examining board appointed by the Government on these principles, composed of persons who had no gain to make out of the candidates, would be a much more satisfactory state of things than any which has obtained up to the present. One of the main points which we wish to urge upon you in connexion with our scheme is the absolute necessity for a man to have actual practical experience before he presents himself as a candidate. The present certificate is in its way very good, but if so purely theoretical an examination is adhered to it will only result in a great number of weak inspectors, unqualified for the positions they have to fill, being appointed. We do not wish to claim an undue share of representation for the Sanitary Inspectors' Association, but we do think that we are entitled to be represented on any board of examiners that may be established. It is of great importance that these posts should be held by men who have had actual practical experience of the work of the men they are called upon to examine.

Sir WALTER FOSTER: I think it will be my duty to say a word or two with reference to the actual position of the Board in this matter. I did not exactly understand that the object

³ Mr. Key's method has been applied already to four hospitals or infirmaries, to some twenty-four large schools, and to several other large buildings, as cloth factories, police-courts, public libraries, and so on, while further installations are being provided for in fifteen similar buildings at the present time.

of your visit to-day was in reference to the form in which the proposed examining body should be constituted. I think, therefore, I had better point out the exact position in which we stand. The fact is that we are placed by statute in the position of having to recognise some body which shall examine and grant certificates to sanitary inspectors. The clause in the statute is as follows: "A sanitary inspector appointed after Jan. 1st, 1895, shall be holder of a certificate, of such body as the Local Government Board may from time to time approve, that he has by examination shown himself competent for such office." Well, now, hitherto the Local Government Board has been in the habit of accepting, as a temporary provision purely, the certificates of the Sanitary Institute, who have constituted themselves an examining body and elaborated a scheme of examination. Up to the present time they have continued to hold examinations and grant certificates to gentlemen desirous of following your calling. But it must be evident that this temporary expedient is not one which in the very nature of things could become permanent, because other bodies have come into existence, have obtained powers and Articles of Incorporation, and are desirous of holding examinations and granting certificates. They naturally wish that they should have a chance alongside of others. One of the first experiences I had on coming to this office was to have applications made to me from such bodies to be allowed to enter the field. The probability is that when the law is altered these certificates will be required not only in London, but in every part of Great Britain, so that in course of time there will be a great number of persons holding these certificates. It is therefore of the first importance that the certificates should be of the highest possible order. It must be obvious to you that the position of the Local Government Board is such that we have to take a certain line of action. In the first place it would be impossible for any Minister here to guarantee to the body at present having the monopoly of holding examinations that such body should retain the monopoly in the future, because a succeeding Minister might come in and say, "Such and such a body is as capable of granting certificates as you are, and I shall give them power to do so." And so in course of time you would have the most deplorable state of things possible—viz., competition between two or more examining bodies. Competition in examination is always injurious in its effects, because the tendency inevitably is for each competing body to lower the standard of examination in order to attract candidates. It is the general experience of all teachers that, whilst competition in teaching in the very nature of things tends to elevate the character of the teaching, all examining competition tends to deteriorate the character of such examining. These principles are not theoretical—I have seen them in actual practice in the medical profession; and I have been very anxious that the sanitary inspectors, as a branch of the great health army of this country, should not be placed in the same position and be overtaken by the same difficulties as gentlemen in my own profession have been through a competition of examinations. For these reasons the Board felt that it would be fatal to give to a number of bodies the power to grant these certificates. The question then arose: Is the Sanitary Institute to go on having the monopoly of conducting these examinations? Well, in the face of other applications and other claims to public consideration, I could not see my way to allowing the Sanitary Institute to continue indefinitely in the exercise of these examining functions. I therefore suggested that all the societies should meet together and form a Joint Board which should be established on such a basis as to be permanent and not likely to be disturbed in the future. One essential characteristic of such a body was that it should represent all the other bodies which were themselves competent to grant certificates. Another is that it should be able in the future to receive into itself any body which might become competent to grant them. In this way a Joint Board would be formed which would represent all other societies and associations so completely that no Minister in the future would feel justified in putting a new body into the field to compete with it, because such new body could join with and be represented on the Joint Board. We have had a good many difficulties to contend with in forming this Joint Board. It seemed to me that the remarks of Sir Benjamin Richardson as to the limited company idea were somewhat misleading. It was suggested that the body to be formed might be incorporated under articles and so get a corporate existence which it would not get otherwise. Of

course, it would not be for trade purposes. That particular form is not necessarily unalterable, and if any great objections to it should arise hereafter I do not think there would be any insuperable difficulty in altering it. It would bind the Joint Board down to certain definite purposes, and to these purposes only, in conducting their work as long as they remain incorporated. It seems to me that if such a board be constituted: 1. It must be an examining body and in no sense a teaching body. 2. It must give certificates for the purpose of qualifying gentlemen as they have been qualified hitherto, and those who possess certificates already will in no wise be injured, as their certificates will be held to be equal in value to the new ones. 3. The several bodies at present existing in connexion with the training of sanitary inspectors and the teaching of sanitary science must as far as possible be recognised by this Joint Board. In constituting this body we must try to deal equitably with the various societies concerned. 4. This Joint Board must have the power of adding to itself from time to time new bodies; just as in the case of the General Medical Council Parliament has recognised that gentlemen already possessing qualifications as medical men should have the power of electing representatives to sit on that Council, so in future sanitary inspectors might be represented. You suggest to me that the Joint Board ought to contain some men who have practical experience in the work. I certainly agree with you in that. I may point out to you that we have no statutory powers to do what the Board of Trade does, and even if we were to do as you suggest a body so formed would not, in my opinion, be in any way so satisfactory as a body formed by the mutual combination of outside societies.

A SANITARY INSPECTOR: I think the Sanitary Inspectors' Association feel that they have been left out in the cold in this matter. They have never been in any way consulted.

SIR WALTER FOSTER: The difficulty, you see, is this—that you are not as a body of sanitary inspectors registered, and are, therefore, incompetent for the moment to be represented on the Joint Board. But I have considered, and I will again consider, whether there is any means by which a body like yourselves could properly be represented on the Joint Board. If there is you may be assured that no effort will be spared on my part to find it.

LORD CHELMSFORD then moved a vote of thanks to Sir Walter Foster for having received the deputation.

MR. PERCY THORNTON, M.P., seconded it, and the deputation withdrew.

KING'S COLLEGE HOSPITAL FESTIVAL DINNER.

THE AMERICAN AMBASSADOR ON "A SOCIAL DUTY."

THE festival dinner of King's College Hospital was held at the Whitehall Rooms of the Hotel Métropole on Wednesday, May 1st. His Excellency the Hon. Thomas F. Bayard, Ambassador of the United States, who presided, said that a hundred and fifty years ago a learned judge, Sir Michael Foster, defined a dangerous criminal as one whose heart was totally devoid of social duty, who was fatally bent on mischief. He said that King's College Hospital presented a complete antithesis; it was a safeguard—a fortress. The feeling which originated it, the feeling which maintained and continued it, was not mere sentiment, but was a force of social safety. It had been questioned whether the State should officially look to the rectification of the inequalities of fortune, whether the State should take these things in charge officially, or whether another and broader spirit should assist to equalise the fate of humanity. He said that the hospital sprang from King's College, and from the Medical School of King's College. Patients wanted the Medical School, and then came the hospital: the demand created the supply. On the other hand, he held that officialism begets a certain stiffness of joints far short of the needs of the case. Hospitals, he maintained, should rely upon the voluntary principle of benevolence, they should be guided by the human principle of the relationship and brotherhood of mankind. Admission to a hospital should be untrammelled by any law but the brotherhood of humanity; no question should be asked but "Do you need our aid." With this rule nothing more democratic or humane could be imagined. For the State to levy taxes for

the support of hospitals, arithmetically and by mere officialism, would not meet the case. Something higher was needed—viz., the generation of personal impulse. Humanity was needed to supplement the harsh spirit of the law. Financial assistance was needful, but it only supplied the machinery, not the motive force. Money was wanted in every hospital, but what was of greater value was the force of personal benevolence, of individual kindness, which constituted the true strength of any system of government. The potency of this helped the patient after he had left the hospital; the sense of the benevolent attention he had received lingered in the mind of the recipient and made him a safe member of society. After visiting King's College Hospital he came away penetrated by the atmosphere of thought and feeling which pervaded it. It was impossible to conceive that officialism or State aid could help in producing this result, which he believed could only have developed under a voluntary system. In this it must be remembered that there was advantage to the helpers as well as to those helped. In one year the beds of the hospital ministered to the needs of 25,000 cases—a number equal to the regular army of the United States. Oliver Wendell Holmes had drawn a picture of two armies, one having the motto, "Our duty is to save," and this one represented the true force and value of those engaged in hospital work. Later in the evening, in responding to the toast of "The Chairman," he said that his part in life was to consider human government, and that he believed the strongest force in mankind was sympathy. He held that the affections of mankind are stronger than their passions. Passions flash and burn out, but the greater part of the world's forces are the human sympathies, which possess a permanence and endurance lacking in passion. He extolled the steady, serene, unscorching influence of human relationship to suffering, as compared with the passionate demands for power and domination, which were opposed to sympathy. He thought that in national affairs liberty might constitute a source of danger. If liberty made for human advancement it was well, but otherwise dangerous results might follow. What was the future of a nation of men set free unless there was an instinct to set free liberty to the advantage of all by human sympathy and human dependence? The object to be looked for should be the cultivation of a feeling in the weakest and humblest that all hearts were enlisted for their welfare.

MIDWIVES REGISTRATION BILL.

THE following is the text of the Bill intituled an Act for the Compulsory Registration of Midwives introduced in the House of Lords by Lord Balfour of Burleigh on April 30th:—

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. This Act may for all purposes be cited as the Midwives Act, 1895.

2. In this Act—

The term "midwife" means a woman who undertakes to attend cases of natural labour without the direct supervision of a medical practitioner.

"Midwives Register" means a register of midwives kept in pursuance of this Act.

"Midwives Board" means the board constituted under this Act for the purpose of carrying out the provisions of the Act, subject to the approval of the General Medical Council.

3.—(1.) From and after Jan. 1st, 1896, no woman shall be entitled to take or use the name or title of midwife (either alone or in combination with any other word or words), or any name, title, addition, or description implying that she is registered under this Act, or is specially qualified to act as a midwife, unless she be registered under this Act.

(2.) Any person who after Jan. 1st, 1896, not being registered under this Act, shall take or use the name of midwife, or any such other name, title, addition, or description as aforesaid, shall be liable on summary conviction to a fine not exceeding five pounds, provided that nothing in this section shall apply to legally qualified medical practitioners.

(3.) No woman shall be placed on the Midwives Register until she shall have complied with the rules and regulations

for admission to registration to be laid down in pursuance of the terms of this Act by the Midwives Board, acting under the supervision of the General Medical Council.

4. A woman registered under this Act shall be entitled to act as a midwife in England and Wales. From and after the first day of January, one thousand eight hundred and ninety-six, no woman shall be entitled to recover any fee or charge in any court for attendance or service rendered as a midwife unless such woman be registered under this Act, and the certificate of registration under this Act shall be a certificate entitling a woman to act as a midwife in cases of natural labour only, in accordance with the prescribed regulations made in pursuance of the terms of this Act. A certificate under this Act shall not confer upon any woman any right or title to be registered under the Medical Act, 1858, or the Acts amending the same, in respect of such certificate, or to assume any name, title, or designation implying that she is by law recognised as a licentiate or practitioner in medicine or surgery, or that she is qualified to grant a certificate of death or of still-birth.

5. Any woman who at the passing of this Act is in *bona-fide* practice as a midwife, or has obtained a certificate in midwifery from some hospital or workhouse infirmary, or from the Royal College of Physicians of Ireland, or from the Obstetrical Society of London, or such other certificate as may be approved by the General Medical Council, and claims to be registered before the expiration of two years from the passing of this Act, and produces the prescribed evidence of her title to be so registered (such title to be determined by the General Medical Council), shall be entered on the Midwives Register at such reduced fee as the Midwives Board shall prescribe.

6. Within six months from the passing of this Act a Midwives Board shall be formed, which shall consist of twelve registered medical practitioners, three to be appointed by the Royal College of Physicians of London, three by the Royal College of Surgeons of England, three by the Society of Apothecaries, and three by the Incorporated Midwives Institute. One-fourth of the members of the board shall annually retire, but shall be eligible for re-election after the lapse of one year. The duties of the Midwives Board shall be as follow:—

(a) To make rules for conducting and superintending the examinations.

(b) To conduct the examinations and appoint, if necessary, assistant examiners.

(c) To decide upon the places where and the times when examinations shall be held.

(d) To frame for approval by the General Medical Council rules regulating the admission to the register of women already in *bona-fide* practice as midwives at the passing of this Act.

(e) To prepare annually a general register of midwives.

(f) To frame for approval by the General Medical Council rules for regulating the practice of midwives.

(g) To decide upon the removal from the register of the name of any midwife for cause shown, and upon the restoration to the register of the name of any such midwife so removed.

(h) To fill up any casual vacancies in the Midwives Board that may occur.

(i) And generally to do any such duty as may be necessary for the due and proper carrying out of the provisions of the Act.

7. For the purpose of the examination of women desiring to act as midwives the Midwives Board shall, as soon as may be after the passing of this Act, frame, subject to the approval of the General Medical Council, rules regulating the conditions of admission to examinations, the course of study to be pursued previous to examination, the method, the periods, and the subjects of such examination, and the general standard to be attained by women passing the examination.

The General Medical Council shall submit the rules approved by them to the Privy Council for confirmation, and the rules when so confirmed shall be forthwith officially published under the superintendence of Her Majesty's Stationery Office. In the event of the General Medical Council failing to perform the duties entrusted to it under this Act, the Privy Council shall invite some other suitable body to undertake these duties, or shall itself forthwith proceed to do so.

8. There shall be payable by every woman presenting herself for examination a fee of two guineas. Should a candidate fail to pass, then for her second or any subsequent

examination the fee shall be half a guinea. In respect of registration, the fee shall be five shillings. All fees paid by midwives or by candidates for examination shall be paid to the Midwives Board. Such board shall devote such fees firstly to the payments connected with the examination and registration, secondly to the general expenses of the board.

9. The Midwives Board shall provide by their regulations for the keeping, and the publication from time to time, of a General Register of Midwives.

10. The Midwives Board shall every year cause a new edition of the register kept by them under this Act to be printed and published, and a copy of such register for the time being shall be evidence in all courts that the women therein specified are registered according to the provisions of this Act; and the absence of the name of any woman from such copy shall be evidence, until the contrary be made to appear, that such woman is not registered according to the provisions of this Act. Provided always, that in the case of any woman whose name does not appear in such copy, a certified copy under the hand of the registrar of the entry of the name of such woman on the register shall be evidence that such woman is registered under the provisions of this Act.

11. The Midwives Board shall appoint the registrar, who may also act as secretary to the board. He shall be charged with the custody of the register.

12. Each medical officer of health throughout England and Wales shall be supplied with a copy of the register from year to year, and he shall keep this register accessible at all reasonable times for public inspection. Such medical officer of health, or other registered medical practitioner as the local authority may appoint, shall be the local supervising authority over midwives in his district. It shall be his duty to report to the Midwives Board any case of malpraxis, negligence, or misconduct on the part of a midwife in his district which has come to his knowledge. For his services he shall receive such fees as the Midwives Board shall determine. No mid-

wife shall commence practice in any district until she has first produced her certificates to the medical officer of health for the district in which she purposes to practice.

13. The registrar of deaths for the district shall at once report to the Midwives Board the death of any midwife in his district, so that her name may be immediately erased by the registrar from the register.

14. Any woman who wilfully procures or attempts to procure herself to be placed on the register of midwives by making or producing, or causing to be made or produced, any false or fraudulent declaration, certificate, or representation, either in writing or otherwise, and any person assisting her therein, shall be deemed guilty of a misdemeanour, and shall on conviction thereof be liable to a fine not exceeding £10, or to be imprisoned with or without hard labour for any term not exceeding three months.

15. Any registrar who wilfully makes or causes to be made any falsification in any matter relating to the register of midwives shall be deemed guilty of a misdemeanour and shall be liable to a fine not exceeding £20, or to be imprisoned with or without hard labour for any term not exceeding six months.

16. Any offences under this Act punishable on summary conviction may be prosecuted, and any fine under this Act recoverable on summary conviction may be recovered, in manner provided by the Summary Jurisdiction Acts.

A prosecution for an offence under this Act shall not be instituted by a private person except with the consent of the Attorney-General, but may be instituted by a county council or the council of a municipal borough. The expenses of any prosecution shall be defrayed out of the county fund of the district where the prosecution takes place.

17. Where any woman deems herself aggrieved by any order, conviction, judgment, or determination of, or by any matter or thing done under this Act by any court of summary jurisdiction, such woman may appeal therefrom to the court of quarter sessions.

18. This Act shall not extend to Scotland or Ireland.

"SO NEAR AND YET SO FAR!"

A CORRESPONDENT sends us a photograph which we reproduce. Professor Montani is evidently a philanthropist of the highest order. He may be, as per advertisement, consulted free of charge from 10 A.M. to 9 P.M., we sup-

On the right-hand side of the picture the reader may see a shadowy pair of legs walking on the pavement. The camera, as is well known, now occupies the place hitherto taken by the second-sighted people who existed among the ancient Greeks and are still found among the Highlanders—that is to say, it sees things which are invisible to the ordinary eye. If the seer saw only the legs of a

pose, but the photograph does not go quite far enough. For a man of this marked kindness of heart, however, he exhibits a *hauteur* and exclusiveness which are even painful. "Professor Montani has no connexion with the Surgery next door." This notice is thoughtful in one way; for it saves the owner of the "surgery next door" from putting up a like statement.

person, the upper parts of the body being shrouded in a mist, it was a presage of his early death. So Theoclymenus, the second-sighted man, says in the *Odyssey* before the slaying of the suitors: "Ah! wretched man, what woe is this ye suffer; for in night are shrouded your heads, and faces, and knees!" Whether the presentiment is about to be fulfilled for the owner of these legs we are unable to say.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

River Tyne Port Sanitary Authority.—Mr. Henry Armstrong reports that no cases of cholera were brought into the waters of his district during 1894, although in two ships arriving indirectly from Jeddah there had been during the voyage 100 and 111 cases of cholera respectively. The time and energy of the port sanitary officials were both greatly taxed by night and day, there being no less than 330 arrivals from cholera-infected ports during the months of August and September. The new disinfecting hulk is now in use. It contains tanks for perchloride of mercury solution, a steam disinfecting apparatus, and a store of liquefied sulphurous acid. There was a marked falling off in the number of emigrants passing through the Tyne Port during 1894 as compared with the previous year, the numbers being 193 and 1015 respectively. The emigrant vessels are visited by the inspectors on arrival and kept under supervision whilst in port. During the year under review there were 6970 coasters and 5073 foreign vessels inspected, and among the coasters we note with pleasure that many were fishing craft. The importance of controlling the sanitary condition of the fishing vessels is seen from the fact that there arrived in the waters of the port during 1894, 5765 trawlers and 9802 herring boats. Large consignments of herring and other fish come, Mr. Armstrong reports, from Denmark, Norway, and Sweden. Twenty-four cattle ships arrived in the Tyne in a filthy condition after having landed cattle elsewhere, and all these vessels were cleansed under the inspector's supervision.

Cheltenham Urban Sanitary District.—The general death-rate of this district was for last year 14·93 per 1000, as against an average for the ten previous years of 17·40. The infantile mortality was 128 per 1000 births, and the zymotic death-rate 0·53 per 1000 living. Cheltenham has provided a public abattoir, but apparently it does not find favour in the eyes of the butchers, and there is no power to close the private slaughter-houses. Dr. J. H. Garrett observes that some of the twenty-six registered slaughter-houses are mere hovels, quite unfit for the purposes for which they are used. We notice that Dr. Garrett publishes in his report a list of those butchers who during the year have made use of the abattoir—a step which may, we imagine, have good results. From the standpoint of the public health and the prevention of cruelty to animals there can be no two opinions as to the desirability of a public abattoir. An additional water-supply for Cheltenham from the river Severn at Tewkesbury has now been introduced, new filters have been provided, and the water proved on chemical analysis to be, Dr. Garrett states, superior in quality to that delivered from Dowdeswell. The Severn water is supplied in separate pipes and has been used for the most part for street watering, baths, &c. Steps are now to be taken to increase the purity of the Dowdeswell supply. There are still, it appears, some 3000 houses in Cheltenham supplied with water from shallow wells sunk in sand and with old sewers and house drains running near. The quality of the water in these wells is, Dr. Garrett observes, subject to peculiar and dangerous variation. We can well believe it, and we trust Dr. Garrett will be successful in his attempt to get them all closed.

Hull and Goole Port Sanitary District.—In relating the detailed work of his department during 1894 Dr. Wright Mason reports that in eighteen vessels the bow lockers were used for storing paints, leads, &c., but that these breaches of the regulations were remedied before the vessels left Hull. In several lighters lying in the docks foul bilges were discovered, and steps were taken to abate the nuisance. During 1894 there were but 19,309 emigrants passing through the port *en route* for America, as against 46,553 during 1893. As regards water-supply eighty-three vessels were found to have taken it in at a cholera-infected port, and all the tanks thus supplied were at once emptied and cleansed. In the case of some other vessels samples of water were submitted to chemical analysis and pronounced unfit for consumption. It would have been very instructive could some of these samples have been submitted to bacteriological examination. Dr. Mason makes a suggestion, in which we cordially concur,

that in the construction of ships attention should be directed to the more modern requirements of sanitation.

Tainmouth Urban Sanitary District.—Dr. F. Cecil Piggott, while referring in his current annual report to the subject of enteric fever, furnishes some evidence which tends to incriminate certain mussels or cockles as having been the cause of four, if not seven, of the cases. The four patients in question had each partaken of the shellfish within fourteen days of attack, and the other three were intimately connected with the fish trade. All these cases were inexplicable on a thesis of water- or milk-borne infection. The shellfish under suspicion were, it appears, obtained from the river Teign, near the outfall of a drain leading from the fever hospital, in which was a patient suffering from enteric fever. It is impossible, Dr. Piggott remarks, to be certain that the excrement had been properly disinfected. The circumstances are interesting and well worth recording, more especially if the shellfish were eaten raw and not cooked.

Sunderland Port Sanitary District.—Some idea of the very salutary effect which the recent cholera prevalence in Europe had in awakening port sanitary authorities to greater efforts may be obtained from Mr. John C. Wood's annual report for 1894. He states that during the year in question, although 2688 vessels were inspected by the sanitary inspector, it was only on two occasions that written notices had to be served for the abatement of nuisances. Defects were, no doubt, detected in many more instances, but it speaks well for the energy of the sanitary authority, and more especially for the tact of its officers, that the machinery works with so little friction. The vessels which were in the best sanitary condition were the Dutch and Danish; of the Spanish, Greek, and Belgian vessels a large percentage were insanitary.

Uxbridge Rural Sanitary District.—The Uxbridge Joint Hospital is the hospital provision used by this district, and in regard to it Mr. Charles Roberts observes that it would be better could the different diseases be more widely separated and nurses appointed for each; also, he remarks, it would be beneficial if patients when convalescent could be isolated for a time before returning to their own homes, as it sometimes happens that infection is carried to their relatives in spite of all precautions taken by the staff. By this we infer that Mr. Roberts advocates the passing of patients through a convalescent home—a course which to some degree is practised by the Metropolitan Asylums Board. As to the value of such a course from the point of view of complete recovery there can be little doubt, but we fear that even with these precautions return cases will from time to time occur.

Torrey Urban Sanitary District.—The infantile mortality in this district was, during 1894, 164 per 1000 births, and Mr. F. H. V. Grosholz, in referring to the causes of such mortality, impresses upon mothers the importance of paying proper regard to health during pregnancy. He also draws the attention of the council to the desirability of employing a trained nurse to instruct the poor in the matter of feeding, clothing, and general care. This, of course, means that the sanitary authority should aid in educating the poor in the intelligent care of their children, and certainly it is only by some such means as this that a lasting diminution can be made in the infantile mortality of the country.

Aberdeen Urban Sanitary District.—Among the cases of small-pox which occurred in the district during the latter part of 1893 and the earlier months of 1894 Mr. Arnall Jones reports that one patient probably contracted the disease by acting as bearer in the funeral of a person dead from small-pox, while two other cases occurred among those employed in destroying infected clothing and bedding.

King's Norton Rural Sanitary District.—Dr. Francis Hollingshead, in discussing the protective value of vaccination, records the instance of a vaccinated infant which remained unattacked by small-pox although at the breast of its mother, who was suffering from small-pox at a small-pox hospital. Apparently no one could be found to take care of the child during its mother's illness. Dr. Hollingshead found that school closure for measles was attended with beneficial results.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6893 births and 3551 deaths were registered during the week ending May 4th. The annual rate of mortality in these towns,

which had declined in the eight preceding weeks from 35.0 to 17.9 per 1000, further fell last week to 17.5. In London the rate was equal to 16.6 per 1000, while it averaged 18.1 in the thirty-two provincial towns. The lowest rates in these towns were 10.6 in Nottingham, 11.9 in Portsmouth, 12.4 in Leicester, 12.6 in Huddersfield, and 12.7 in West Ham; the highest rates were 22.9 in Blackburn, 23.2 in Liverpool, 23.3 in Oldham, 23.9 in Manchester, and 26.7 in Burnley. The 3551 deaths included 305 which were referred to the principal zymotic diseases, against 336 and 327 in the two preceding weeks; of these, 90 resulted from whooping-cough, 80 from measles, 49 from diphtheria, 39 from diarrhoea, 24 from "fever" (principally enteric), 22 from scarlet fever, and 1 from small-pox. No fatal case of any of these diseases occurred last week in Halifax; in the other towns they caused the lowest death-rates in Bristol, Bradford, Brighton, Leeds, and Sunderland, and the highest rates in Bolton, Burnley, Plymouth, Salford, and Preston. The greatest mortality from measles occurred in Plymouth, Manchester, and Bolton; and from whooping-cough in Plymouth, Birkenhead, Burnley, Preston, Salford, and Wolverhampton. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 49 deaths from diphtheria included 29 in London, 5 in Birmingham, 3 in Leeds, 2 in Birkenhead, and 2 in Sheffield. One fatal case of small-pox was registered in London, but not one in any of the thirty-two large provincial towns. There were 34 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 4th inst., against 47, 35, and 37 at the end of the three preceding weeks; 8 new cases were admitted during the week, against 9, 4, and 12 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1413, against 1463, 1514, and 1469 on the three preceding Saturdays; 107 new cases were admitted during the week, against 117, 162, and 132 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 389 and 341 in the two preceding weeks, further declined to 290 last week, and were 55 below the corrected average. The causes of 58, or 1.6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Newcastle-upon-Tyne, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Burnley, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 24.7 to 20.6 per 1000, rose again to 20.9 during the week ending May 4th, and was 3.4 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15.6 in Dundee and 17.4 in Paisley to 25.1 in Greenock and 25.7 in Perth. The 602 deaths in these towns included 27 which were referred to measles, 17 to whooping-cough, 13 to diarrhoea, 7 to scarlet fever, 4 to diphtheria, 3 to "fever," and not one to small-pox. In all, 71 deaths resulted from these principal zymotic diseases, against 78 and 73 in the two preceding weeks. These 71 deaths were equal to an annual rate of 2.5 per 1000, which was 1.0 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 30, 32, and 26 in the three preceding weeks, were 27 last week, of which 8 occurred in Edinburgh, 6 in Glasgow, 6 in Leith, and 4 in Aberdeen. The deaths referred to whooping-cough, which had been 17 and 24 in the two preceding weeks, declined again to 17 last week, and included 14 in Glasgow. The 7 fatal cases of scarlet fever exceeded the number recorded in any recent week, and included 4 in Glasgow and 2 in Edinburgh. The deaths from diphtheria, which had been 7 and 3 in the two preceding weeks, were 4 last week, of which 2 occurred in Glasgow. The 3 fatal cases of "fever" corresponded with the number in the preceding week, and included 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 132 and 145 in the two preceding weeks, declined to 124 last week, but were 29 above

the number in the corresponding period of last year. The causes of 48, or more than 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29.7 and 27.0 per 1000 in the two preceding weeks, rose again to 27.3 during the week ending May 4th. During the past five weeks of the current quarter the death-rate in the city has averaged 31.1 per 1000, the rate during the same period being 18.3 in London and 19.5 in Edinburgh. The 183 deaths registered in Dublin during the week under notice showed a slight increase upon the number in the previous week, and included 7 which were referred to the principal zymotic diseases, against 3 and 5 in the two preceding weeks; of these, 4 resulted from whooping-cough, 2 from small-pox, 1 from diphtheria, and not one either from measles, scarlet fever, "fever," or diarrhoea. These 7 deaths were equal to an annual rate of 1.0 per 1000, the zymotic death-rate during the same period being 1.7 in London and 2.7 in Edinburgh. The 4 fatal cases of whooping-cough exceeded the number recorded in any recent week. The deaths referred to small-pox, which had been 1 in each of the two preceding weeks, were 2 last week. The 183 deaths registered in Dublin last week included 29 of infants under one year of age and 50 of persons aged upwards of sixty years; the deaths of infants considerably exceeded the number in the preceding week, while the deaths of elderly persons showed a decline. Five inquest cases and 3 deaths from violence were registered; and 51, or more than a fourth, of the deaths occurred in public institutions. The causes of 21, or more than 11 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1895.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during April in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 5.7 per 1000 of the population, estimated at 4,392,346 persons in the middle of the current year. In the three preceding months the rates had been 7.0, 5.9, and 5.8 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in St. George Hanover-square, Stoke Newington, St. Martin-in-the-Fields, City of London, St. Saviour Southwark, and St. Olave Southwark; while they showed the largest excess in Chelsea, Holborn, Limehouse, Poplar, Rotherhithe, Greenwich, and Plumstead. The prevalence of small-pox in London showed a slight further decline in April, 37 cases being notified during the month, including 9 in Holborn, 8 in Rotherhithe, 6 in Lambeth, and 3 in Islington sanitary areas. The Metropolitan Asylum Hospitals contained 34 small-pox patients at the end of April, against 51, 66, and 54 at the end of the three preceding months; the weekly admissions averaged 7, against 10, 15, and 11 in the three preceding months. The prevalence of scarlet fever in London showed a slight decline from that recorded in the preceding month; this disease was proportionally most prevalent in Chelsea, Limehouse, Poplar, Rotherhithe, Greenwich, Lee, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 1413 scarlet fever patients at the end of April, against 1633, 1569, and 1485 at the end of the three preceding months; the weekly admissions averaged 132, against 148, 141, and 145 in the three preceding months. The prevalence of diphtheria in London showed a further increase during April; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Chelsea, Strand, Whitechapel, Poplar, Rotherhithe, and Camberwell. There were 430 cases of diphtheria under treatment in the Metropolitan Asylum hospitals at the end of April, against 515, 461, and 435 at the end of the three preceding months; the weekly admissions averaged 69, against 71, 50, and 62 in the three preceding months. The prevalence of enteric fever in London showed a slight decline during the month under notice; among the various sanitary areas this disease showed the highest proportional prevalence in Paddington, Marylebone, St. George-in-the-East, and Greenwich. Erysipelas was proportionally most

* Including 23 cases of membranous group.

† Including deaths from membranous group.

prevalent in Kensington, St. Pancras, St. Luke, Bethnal-green, and Lambeth sanitary areas. The 13 cases of puerperal fever notified during April included 3 in St. Pancras, and 2 each in Wandsworth, Greenwich, and Lewisham sanitary areas.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, April 27th, the deaths of 6,170 persons belonging to London were registered, equal to an annual rate of 18.3 per 1000 of the population, against 18.3, 30.3, and 30.0 in the three preceding months. The lowest death-rates during April in the various sanitary areas were 11.1 in Hampstead, 12.2 in Stoke Newington, 13.0 in Lewisham (excluding Penze), 13.8 in Hammersmith, 14.4 in Lee, and 15.2 in Paddington and in Wandsworth; the highest rates were 25.3 in Newington, 25.5 in Holborn, 26.0 in St. Saviour Southwark, 26.7 in St. Giles, 26.9 in St. Luke, 27.1 in St. George-in-the-East, and 29.4 in Strand. During the four weeks of April 516 deaths were referred to the principal zymotic diseases in London; of these, 188 resulted from whooping-cough, 107 from measles, 105 from diphtheria, 53 from diarrhoea, 44 from scarlet fever, and 19 from enteric fever. These 516 deaths were equal to an annual rate of 1.5 per 1000, which corresponded with the rate in each of the two preceding months. The lowest death-rates from these diseases during last month were recorded in Paddington, St. James Westminster, Stoke Newington, Bermondsey, Lee, and Plumstead; and the highest rates in St. Martin-in-the-Fields, Clerkenwell, Shoreditch, Limehouse, Mile End Old Town, Poplar, Rotherhithe, and Battersea sanitary areas. No fatal case of small-pox was registered in London during the month under notice, the corrected average in the corresponding periods of the ten preceding years being 20. The 107 deaths referred to measles were but little more than a third of the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Shoreditch, Limehouse, Mile End Old Town, and Poplar. The 44 fatal cases of scarlet fever were 18 below the corrected average number; the mortality from this disease showed no marked excess last month in any of the sanitary areas. The 105 deaths from diphtheria were slightly below the corrected average number; this disease showed the highest proportional fatality in Kensington, St. Giles, Strand, Shoreditch, Poplar, Battersea, and Camberwell sanitary areas. The 188 fatal cases of whooping-cough were 90 below the corrected average number; among the various sanitary districts this disease showed the highest proportional fatality in Westminster, St. Martin-in-the-Fields, Clerkenwell, Shoreditch, Newington, and Lambeth. The 19 deaths referred to enteric fever were 17 below the corrected average number; there was no marked excess of "fever" mortality last month in any of the sanitary areas. The 53 fatal cases of diarrhoea were within 5 of the corrected average number. In conclusion, it may be stated that the mortality in London during the month under notice from these principal zymotic diseases was as much as 39 per cent. below the average.

Infant mortality in London during April, measured by the proportion of deaths under one year of age to registered births, was equal to 152 per 1000, and exceeded the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Hammersmith, Marylebone, Hackney, Holborn, City of London, and Bethnal Green; and the highest rates in Chelsea, St. George Hanover-square, St. Martin-in-the-Fields, Poplar, St. Saviour Southwark, Newington, and St. Olave Southwark.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR MACLEAN and Surgeon-Captains Keatly and Weir have arrived from India in the *Malabar* on completion of a tour of service. Surgeon-Captain Watson has arrived from Egypt, and Surgeon-Major Michael and Surgeon-Captain Gray have left Egypt on completion of their tour. Surgeon-Major Hughes has been posted to Chatham, and Surgeon-Captain Young to Dublin.

INDIA AND THE INDIAN MEDICAL SERVICES.

Deputy Surgeon-General Sir Joseph Fayrer, M.D., F.R.C.S. Edin., K.O.S.I., Retired List Indian Medical Service, Honorary Physician to the Queen, late President of the Medical Board, India Office, is granted the honorary rank of Surgeon-General.

The following appointments are announced:—Surgeon-Captain J. W. Bullen, M.D., A.M.S., to the Civil Medical Charge of Ranikhet, in addition to his military duties; Surgeon-Captain J. M. Cadell, officiating Civil Surgeon, Sultanpur, to the Medical Charge of the Camp of the Lieutenant-Governor and Chief Commissioner, North-West Provinces and Oudh; Brigade-Surgeon-Lieutenant-Colonels G. Hutcheson, G. McB. Davis, H. T. Brown, and C. F. Pollock to officiate as Principal Medical Officers of the Lahore District, Punjab Frontier Force, Peshawar and Rawalpindi Districts respectively; Surgeon-Major F. C. Chatterji, Civil Surgeon, Philibhit, on being recalled from privilege leave to the Mainpuri District. The following officers of the Army Medical Staff have come out to India in succession to "tour expired" officers:—Surgeon-Lieutenants W. D. Erskine, H. A. Hinge, H. A. Bray, H. S. Thurston, J. G. McNaught, C. T. Samman, J. H. Farmer; Surgeon-Captains J. J. C. Donnet, C. S. Sparkes, R. L. R. McLeod, J. B. Wilson, W. J. Trotter, M. J. Sexton, J. M. Nicholls; Surgeon-Majors R. F. O'Brien, P. J. Dempsey, O. Todd; and Surgeon-Lieutenant-Colonels J. Ring and W. E. Saunders. Surgeon-Major E. S. Brander, Civil Surgeon, is transferred from Mainpuri to Muttra.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Staff-Surgeon J. T. W. S. Kellard to the *Malabar*; Surgeon J. C. Wood to the *Hood*.

VOLUNTEER CORPS.

Artillery: 1st Kent (Eastern Division, Royal Artillery): Surgeon-Lieutenant J. I. Boswell, M.D., resigns his commission. 1st Argyll and Bute: The under-mentioned gentlemen to be Surgeon-Lieutenants: John William Watkin Penney, M.B.; David Johnston Penney, M.B. 1st Cumberland: Surgeon-Lieutenant W. J. Fairlie, M.B., resigns his commission. 1st Durham (Western Division, Royal Artillery): Surgeon-Lieutenant D. F. Todd to be Surgeon-Captain. 5th Lancashire: Surgeon-Captain C. W. Dean resigns his commission. *Royal Engineers*: 1st Aberdeenshire: Surgeon-Lieutenant W. Sinclair, M.B., to be Surgeon-Captain. *Rifle*: 1st Volunteer Battalion the Royal Warwickshire Regiment: Surgeon-Lieutenant W. P. Whitcombe to be Surgeon-Captain. 1st Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant W. E. R. Wood, M.D., to be Surgeon-Captain. 3rd Volunteer Battalion the South Staffordshire Regiment: Surgeon-Lieutenant T. R. Bailey, M.D., resigns his commission. 1st Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Edward Hawkesworth Hackett, Gent., to be Surgeon-Lieutenant. 4th (Perthshire) Volunteer Battalion the Black Watch (Royal Highlanders): Charles William Howatson, M.B., to be Surgeon-Lieutenant. 1st (Ross Highland) Volunteer Battalion Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Colin Mackenzie, Gent., formerly Surgeon-Lieutenant, to be Lieutenant. 6th Volunteer Battalion the Gordon Highlanders: Surgeon-Captain R. S. Turner to be Surgeon-Major; William Robert Duguid, jun., M.B., to be Surgeon-Lieutenant.

DEATH IN THE SERVICES.

Surgeon-Major George Laffan, M.D., Q.U.I., A.M.S., at Belgum, Madras, on the 27th ult. Born in 1845, he graduated in 1876 at Queen's College, Cork, and was appointed a surgeon in the army in the following year. He attained the rank of surgeon-major in 1889. He served in the Soudan Expedition of 1884-85 (medal with clasp and the bronze star), and the expedition to Manipur, 1891 (medal and clasp).

"THE SCOURGE OF INDIA."

Surgeon-Major Perry Marsh, Army Medical Service, has published in the *United Service Magazine* of this month a rejoinder to the article which appeared from Brigade-Surgeon-Lieutenant-Colonel Climo in the preceding number of that journal. The scourge referred to is, as our readers are probably aware, enteric fever, about which we have also had a good deal to say in THE LANCET from time to time. Surgeon-Major Perry Marsh analyses the statements contained in Brigade-Surgeon-Lieutenant-Colonel Climo's

paper and deals with them *seriatim*. He challenges the correctness of the allegation that "the increasing prevalence and mortality from enteric fever in India is the direct consequence of regiments no longer having medical officers serving with them," and makes many strong points by using for the purpose of his argument a number of facts with which our readers and medical officers generally are no doubt acquainted. Surgeon-Major Perry Marsh adverts to the alteration that has taken place in the diagnosis of fever in India of late years as compared with a time when enteric fever was not sufficiently differentiated from other forms of Indian fever, and not recognised as it is now. He dwells upon the influence of youth and recent arrival as very important factors in increasing the susceptibility to this form of fever, and points to the fact that with a short service system the European force in India contains a far greater proportion of this susceptible material—*young and recently arrived men*—than it did formerly. He proves this by statistical evidence which has been sufficiently repeated year after year to leave no doubt; and he also contests the correctness of Brigade-Surgeon-Lieutenant-Colonel Climo's statements as to the influence of the selection of recruits and the invaliding rates of the army of India (which have declined from 40 per 1000 for the ten years ending 1870 to 25.3 per 1000 for 1893). The sanitation and cleanliness of Indian cantonments, from all we can gather, are well attended to—many of them, indeed, are models of cleanliness and neatness. It is outside cantonments, in the native bazaars, that insanitary conditions prevail so extensively. As we have frequently said, however, we are not satisfied with the present system of barrack-room water filtration, and were glad to see that a question was recently asked in the House of Commons about the remarkable improvement that had been effected in diminishing the amount of enteric fever in the French army by the use of their new form of filter. It is surely time that something was done in this respect for our army in India.

THE HOSPITALS FOR FIELD SERVICE IN INDIA.

The late Afghan War gave rise to a reorganisation of the medical service in India and to a complete remodelling of the field service equipment. A field hospital is equipped for 100 beds and it is capable of being divided into four sections, each a complete unit in itself in respect of *matériel* and *personnel*. Each field hospital has a distinguishing number, and the four sections are designated by letters above the field hospital number. Great care has been bestowed upon the provision, arrangement, and packing of stores, medical comforts and medical and surgical appliances, in order to adapt them practically to the requirements of field service. The entire *personnel* of a British field hospital, from the surgeon-major in charge to the junior tent-lascar, consists, inclusively of muleteers, of 294 persons. The latest Medical Department Code for field service in India is generally supposed to be very good and complete. The *Pioneer Mail* of April 18th has a communication descriptive of some of these hospitals, which are termed "model field hospitals," as they left Meerut for service with the Chitral relief force.

VOLUNTEER MEDICAL ASSOCIATION.

The annual mess dinner of this association was held at Limmer's Hotel on Wednesday, April 24th, and a large party of members and guests sat down under the chairmanship of Surgeon-General Don, who presided in the absence of Sir Guyer Hunter. In the various speeches reference was made to the work which had been done by the association, and of the necessity for its support by all volunteer medical officers. It was pointed out that this was the only organisation through which representations could be made to the authorities regarding the objects in which its members were interested. The arrangements for the dinner were admirably carried out by the mess committee and the hon. secretaries, Surgeon-Captain Dundas Grant and Surgeon-Lieutenant A. Eddowes.

THE SMALL-POX OUTBREAK AT CALCUTTA.

According to the latest intelligence from India small-pox is still very prevalent at Calcutta. The epidemic appears to be of a severe character and to have given rise to a good deal of mortality. An enormous number of natives and others have been vaccinated or revaccinated since the disease made its appearance in Calcutta, and the able and energetic public health officer of that city, Dr. Simpson, has been very actively employed in devising and carrying out arrangements in this and other respects for checking the

spread of the disease. There has also been a good deal of cholera of late in Calcutta.

THE DEFENCE OF CHITRAL.

Our readers, in common with the rest of the public, will be glad to learn that the Secretary of State for India in Council has sanctioned the recommendation of the Government of India to grant six months' pay to all ranks of the garrison in recognition of their splendid defence of Chitral Fort. We congratulate all concerned, and especially Surgeon-Major Robertson and Surgeon-Captain Whitchurch on the distinguished part which they played throughout the siege, and have no doubt that both these officers will receive some further recognition of the conspicuous services they have rendered.

Correspondence.

"Audi alteram partem."

"MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS."

To the Editors of THE LANCET.

SIRS.—Mr. Sharp, in his letter in THE LANCET of May 4th, has courteously disclaimed any intention on the part of the School Board to put a slight upon the medical profession by the appointment of scrutineers of medical certificates which are considered doubtful or unsatisfactory by the Board. Yet the results of the Board's action cannot but belie its intentions. The majority of such certificates are filled up *gratuitously* by medical men who act in perfect good faith and with every consideration for the welfare of children, parents, and schools, for they can have no motive for acting otherwise. Mr. Sharp denies that certificates are given as an act of courtesy to the Board. "On the contrary," he says, "they are procured by the parents as evidence of the child's inability to attend school." How procured, he does not apparently inquire. As a matter of fact, the burden of filling them up in large quantities falls chiefly on hospital medical officers, for the same class of children attend Board schools and hospitals alike. The certificates are sent by the Board's officers through the parents to the medical attendant, with a direct request that he will fill them up, or the parents will be summoned and fined. It is, of course, open to the medical man to refuse to do so, and to offer to give evidence on the parents' behalf should a summons be issued. But the poor parent at once objects that even if he escape a fine he will lose a day's work by having to attend the Police-court, and the medical man shares the latter objection. So he endeavours to save the child from possible injury from enforced schooling, the parents from unjust prosecution, and himself from further trouble by giving a certificate. In doing so he also supplies the Board with gratuitous information which it has no legal right to demand. He thus saves the Board from undertaking actions which, were he to give evidence in court, it would entirely lose. Hence, giving a certificate instead of attending to give evidence in court is distinctly an act of courtesy to the Board. It seems therefore a little ungracious of the Board to first exert indirect pressure on medical men to do unpaid work for it, and then to question the value of the work done. The main reasons alleged for these new appointments are that "medical certificates are frequently presented which are unsatisfactory either on account of the vagueness of the terms used, or of a doubt as to the seriousness of the malady from which the child was alleged to be suffering." Whatever opinion the School Board may form on these points, it seems only right that the opinion of a medical man that a child is unfit for school should be respected; at all events, reference should be made to him if the Board is in doubt. The Board, however, thinks otherwise, for quite recently the parents of a boy, who has been under my care for many weeks as an out-patient and for whom I gave a certificate of unfitness to attend school, have been summoned and fined at the Clerkenwell Police-court for not sending him to school. My certificate was rejected by Board and magistrate. I was not called upon to give evidence. The result of such high-handed proceedings by the Board can only be that medical men will absolutely refuse to give

certificates, finding their labour thrown away. The new appointments by the Board will, therefore, become sinecures. It will, however, cause constant chagrin and vexation to medical men to find that their efforts to serve children, parents, and schools are so ill appreciated by the Board. After all, the Board should know that medical men are its best friends. All will agree with Mr. Sharp that the school attendance of a child is by no means a "trivial matter," but one of "vital importance, not merely to the future welfare of the child, but also indirectly to the community generally," especially, I would add, when the child is medically unfit to attend. And of this who are to be the judges?

I am, Sirs, yours faithfully,

LEONARD G. GUTHRIE.

Upper Berkeley-street, W., May 6th, 1895.

"MEDICAL EVIDENCE AT INQUESTS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 4th I notice a communication on the above subject. In an editorial note to Mr. Milligan's explanation you state your opinion "that it would have been advisable to take the evidence of the medical man who first saw the wound." This seems so obvious that one wonders that it is not the universal practice. I can give a case in point. Some time ago I was called to see a man who had been shot. He lived close to my house, so that I was able to attend within a few minutes of the accident. I found the man lying on the floor, with blood spurting from a wound in the neck. As the patient was rapidly bleeding to death, I placed my finger on the wound, and so stopped the flow of blood. Having sent for the ambulance, the man was conveyed to hospital, when the hæmorrhage was found to have ceased, owing no doubt to the fact that I had kept my finger firmly applied to the wound during the whole time since I first saw him. I may state that the patient made an incriminating statement to me against a youth who had fired the shot, saying that it was done intentionally. The youth was afterwards tried for murder and acquitted, there being no evidence to prove that the occurrence was not purely accidental. After making the statement to me the patient never spoke again. He died a few hours afterwards in hospital. The police whom I sent for carefully took my name and address, and that was the last I heard of the matter. The divisional surgeon, who had never seen the man at all until he saw him in the mortuary, was called at the trial, though what value his evidence could have it would be difficult to say. Had I waited until the police sent for me to attend the man would have been dead, but I should have had a fee. As I attended first and sent for the police myself I saved the patient's life for the moment, but received no fee. Although I am satisfied that in this case the wounding was accidental, it is not difficult to imagine that there might have been a grave miscarriage of justice.

I am, Sirs, yours faithfully,

Holloway-road, N., May 6th, 1895.

W. A. MALCOLM.

"THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED."

To the Editors of THE LANCET.

SIRS,—In reference to Mr. Dunlop's letter in THE LANCET of May 4th, it would be as well, perhaps, to remove the impression made by it—viz., that medical men are likely to receive even the utterly inadequate rate of 8d. for each bottle of medicine supplied by them to club patients—by stating at once that, far from receiving 8d., the most they can expect to receive is 3d. a bottle. I have been myself for many years connected with a club whose rate of pay to their medical officers is practically the same as that of the London and Manchester Industrial Assurance Company, and the average amount per bottle received by me over a period of ten years, compiled from accurate statistics kept by my assistant, came to something less than 3d. a bottle. It is true that last year—the year on which Mr. Dunlop's estimate is based—I too received about 9d. a bottle on an average from my club patients, but that was because (owing to the unusual character of the season) I had, in common with so many medical men in all parts of London, only one-third of the usual number of patients requiring attendance—a condition of things not likely to be permanent, and

on which, therefore, it would be dangerous on any matter of moment to base calculations for the future.

I am, Sirs, yours truly,

JOHN BEATTIE CROZIER, M.B., L.R.C.P.

Elgin-avenue, W., May 8th, 1895.

"IRRIGATION AND CLIMATE."

To the Editors of THE LANCET.

SIRS,—In this week's issue of THE LANCET there are some remarks on the effect of irrigation upon the climate of Egypt which raise a question of real interest. Has the climate of Lower Egypt become much damper than it used to be? The answer must be undoubtedly in the affirmative. I was in Cairo for the first time in the winter of 1850, and have been there three times since during the last five or six years. At the former period rain was so rare an occurrence that people gazed at it as at a remarkable phenomenon. During the latter period boats have been actually used at times in the streets of Cairo at periods of heavy rains. These are the facts, and it is probably not difficult to suggest the cause.

I am, Sirs, yours faithfully,

W. H. HALLIDAY.

Oxford and Cambridge Club, Pall Mall, S.W., May 4th, 1895.

"STERILISATION OF MILK."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 20th Dr. Carter, in an able article, calls attention to the vital importance, especially during the summer months, of preparing milk for home consumption which shall agree perfectly with infants and with dyspeptic adults, and which yet shall be neither raw nor boiled. Though he does not say so in so many words, the chief practical advantage of sterilised milk over boiled milk is that it does not cause the constipation usually complained of when mothers are compelled to boil the children's food. I may mention that in some Oriental countries milk is regarded as a mild aperient merely because it is the custom of the natives to drink it when no longer fresh. Dr. Carter commends the adoption of a sterilising machine which sounds desirable in many ways. It is apparently a modification of Professor Soxhlet's sterilising apparatus for milk, which is too little known to English practitioners. This apparatus was brought out in Munich in 1886, and has since then been in constant use in Germany. It has been employed in Egypt for more than three years, and after using it for my own children and for patients I can confidently recommend it as being simple, portable, certain, and inexpensive. (The London agent is Mr. Pearl, 4, Bury-court, St. Mary-axe.) Dr. Carter proposes that the milk-bottles shall be closed with cotton-wool, but the Soxhlet system of providing indiarubber corks, which are sucked into the neck of the bottle during the heating process, is perhaps better. The milk will then keep sweet for several weeks in the corked bottles. The best kind of cork has been invented by Professor Stutzer, and can be obtained from Messrs. Ollendorff-Wilden of Bonn. In order to preserve milk in larger quantities, as in dairies or hospitals, nothing will be found to act much better than an apparatus originally made for breweries, and introduced some three years ago into the Kasr el Aini Hospital by the medical superintendent, Mr. Milton. Formerly it was impossible to keep milk during the summer nights, but now there are no further complaints, and it is even found that the milk will keep for three days in vessels covered by muslin only, provided that the vessels also are previously sterilised. By this machine, made by Messrs. Lawrence and Co. of London, every morning more than 100 pints of hospital milk are rendered innocuous for future consumption in less than fifteen minutes by heating the milk by steam and then rapidly cooling it again.

I am, Sirs, yours faithfully,

Cairo, May 1st, 1895.

F. M. SANDWICH, M.D.

"THE TITLE OF 'DOCTOR.'"

To the Editors of THE LANCET.

SIRS,—Mr. Sewill has hit the nail on the head. The medical profession require two things most urgently: first, that the Medical Acts shall be so amended as to make it a penal offence for persons to practise any branch of medicine.

or surgery, the penalties to be increased substantially for second and third breaches of the Act; and, secondly, a public body or a public officer whose duty it shall be to enforce the provisions of the Act. It is mere waste of time to attempt to draw up a penal clause and endeavour to embrace in it all the titles at present assumed by unqualified men. As soon as the list of titles was drawn up men would invent fresh titles and would continue to practise with impunity. A movement is on foot to ask the British Medical Association to spend a portion of its surplus income in the suppression of quackery; and in the opinion of many thoughtful men such a movement would be likely to prove successful. It is also worth much consideration as to whether the mature experience (as Mr. Victor Horsley suggested in his annual address) of the Medical Defence Union could not be utilised for such an important work. At the present moment what is most required is the focussing of the opinion of the profession on these vital points; and I sincerely hope that ere long an opportunity will be given to those who have taken an interest in them to confer together and if possible draw up a scheme for presentation to the members of the profession.

I am, Sirs, faithfully yours,

T. GARRETT HORDER.

Cardiff, April 29th, 1895.

To the Editors of THE LANCET.

SIRS,—There is a fact which seems to have been overlooked which I venture to think cuts the ground entirely from under Dr. Campbell Black's feet. It is that the Society of Apothecaries successfully claims for its Licentiates the legal right to style themselves Doctor. This being so, Dr. Campbell Black's contention that the coveted title belongs only to men who have taken the University degree of Doctor falls to the ground, and with it, it seems to me, ought to fall his protests. For it is manifestly absurd to deny to (e.g.) the M.R.C.S., L.R.C.P. a title which is accorded to the certainly not superior L.S.A. For my part I should be in perfect sympathy with Dr. Campbell Black's desire to limit the title to the *bonâ fide* M.D., were the opportunity of acquiring that degree given, as it should be, to every duly qualified man. But under existing conditions, while I intend never to assume the title, I shall yet always expect to receive it, at least from my patients, and shall certainly feel no resentment towards those who, perhaps more logical and more courageous, do assume it. Sauce for the goose should be sauce for the gander; and while the L.S.A. takes the title as his right, and the M.B. of every recognised University, however mediocre, receives it, even in the pages of THE LANCET, "by courtesy," it is ridiculous to expect the diplomate of a College of Physicians to abstain from endeavouring to minimise so glaring an injustice. He uses the title, therefore, and establishes an impregnable defence by appealing to immemorial custom and the universally received interpretation of the word physician.

I am, Sirs, yours faithfully,

PALMAM QUI MERUIT.

May 3rd, 1895.

To the Editors of THE LANCET.

SIRS,—Dr. Campbell Black evidently has to encounter some rather subtle logicians upon what, after all, should appear a most simple question, and it is one which threatens to drift into a question rather of etymological than of practical importance. If, however, Dr. Black sticks to his big gun—that is, as he states, that "a doctorate is a University degree"—no collateral issues, such, for instance, as the distinction between a doctor and a physician, can touch the point, as we have nothing whatever to do with these considerations. Nothing can alter the fact that a University degree confers the title of "doctor," whereas a Licentiate or otherwise does not. It has been attempted in some quarters to point out that a large number of the medical corporations address their diplomates as "doctor," and that medical men address one another as such, and, further, that the public use the term in a general sense. None of these considerations, moreover, touch the point. The real question is, Has a non-graduate any right to *dub himself* "doctor"? He is clearly not responsible for what others do. The writer remembers many years ago a commoner who, upon being driven to a dinner party in a cab, was addressed by the cabman as "My Lord," the cabman presumably thinking his fare, who happened to be a person of aristocratic appearance and demeanour, must be a nobleman. Surely nobody could contend on this ground that the fare would be entitled to announce himself thus.

By parity of reasoning non-graduates have no claim to dub themselves "doctor" on brass or otherwise, whatever others may do for them. If it is otherwise, University degrees, so far as the title is concerned, are absolutely null and void—in other words, they are useless, which is obviously unfair to those who have gone to the expense and trouble of obtaining them, and probably more with the object of obtaining a title than anything else. I am, Sirs, yours, &c.,

London, May 4th, 1895.

L.R.C.P. EDIN.

* * This correspondence must now cease.—ED. L.

"PUBLIC AND PRIVATE VACCINATION."

To the Editors of THE LANCET.

SIRS,—I fully endorse the complaint of several of your contributors who are public vaccinators, that much vaccination is done insufficiently, according to the wishes of mothers, rather than, as it should be, with the sole view of safeguarding the patients from small-pox. Indeed, until the number of successful vesicles appears on the certificate, which could readily be the case, such insufficiency is sure to continue. It is a very easy remedy, and could almost at once be put into force. I tried to get this information from the registrar of my district, but he tells me that, on asking, the reply he got was the question, "What business it was of his?"

I am, Sirs, yours truly,

ANOTHER PUBLIC VACCINATOR.

May 3rd, 1895.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Street Noises.

REFERRING to the annotation in last week's LANCET on Street Noises, it may be stated that in Liverpool we have for some years past possessed under a local Act very summary powers of dealing with the noises made by street musicians or singers. A householder may personally, or by a servant or police constable require a street musician to depart beyond the hearing of such householder, which would mean a very considerable distance. Refusal to comply with this very reasonable request subjects the musician to a fine not exceeding 40s. and costs, and it has been found necessary to summon some few of these pests for persisting to play in or near a street largely inhabited by members of the medical profession. In addition to the reasons suggested in the annotation why a licence should be required of these gentry, another might be added—the large earnings acquired by them. Whether it be honestly earned, or be more correctly black-mail, it is no secret that the amount earned by the owner of a piano-organ is very large. A large number of medical practitioners reside within short distances of various churches whose monotonous bells tolling for nearly half an hour are a terrible infliction. But the most cruel of all pests is the ringing of changes on a peal of bells at a late hour in the evening, the clashing and clanging being incessant for, it may be, two hours. It is no consolation to the physician or surgeon, who has been trying to listen to patients, to read, or to write during this period, to learn that it was "a true peal of grandsire caters which came round in two hours and thirty-seven minutes." If change-ringing and practice be desirable, might it not be done, say, on Saturday afternoon, when the annoyance would be less?

The Assizes.

Mr. Justice Hawkins is presiding in the Crown Court at the present assizes. The calendar contains the names of forty-four prisoners. Among these, one is charged with murder, one with manslaughter, and one with shooting with intent. Several women are charged with a serious assault on a boy twelve years of age because he gave evidence at the last assize against a prisoner for maliciously wounding a woman. He was so seriously hurt that he had to be taken to the Royal Infirmary. Quite apart from the nature of the injury, assaulting or even intimidating a witness is a very grave offence.

Gift of a New Park.

Another fine breathing-place has been presented to this city by an anonymous donor. It takes the form of a park, situated at Wavertree, an eastern suburb of Liverpool, noted as the residence of the poetess, Felicia Hemans. The value

of the gift, which is of considerable extent, is stated to be over £80,000. Such gifts are, however, invaluable.

May 8th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Infirmary Site, Newcastle-upon-Tyne.

By a large majority—33 to 10—Mr. Alderman Henry Newton's motion that the corporation should grant the infirmary governor's request to build a new hospital on a portion of the town moor, on the condition that an equal area should be added to the moor, has been negatived. It is believed that the action of the town council fairly represents the feeling of the citizens, and the objections against building upon any part of the moor is undoubtedly a strong one. It will occur to many, however, that if by placing the Leazes site at the disposal of the infirmary committee the area of the moor would not have been curtailed, the strongest reason for not granting the request of the infirmary committee was satisfactorily met. The Royal Infirmary is undoubtedly in a strait; its present accommodation is inadequate and it would be exceedingly difficult to build upon the present site such a hospital as is required. The staff would be content to remain where they are, in the very centre of the town, if additional land could be procured, but hitherto this has been found impossible. It is doubtful whether the corporation would be willing to curtail the scope of the cattle market for the benefit of the infirmary even if they had the power to do so, and in no other direction can the present site be added to.

New Charter for the University of Durham.

It is understood that the petition of the University to the Queen in Council has been granted and that a new Charter is about to be given. If this should be true the University will then be able to grant degrees to women in all the faculties with the exception of theology. Why women should not be encouraged to study theology is a little difficult to understand. It cannot be because the fair sex are not interested in the subject, for the majority of almost every Church of England congregation consists of women—perhaps the reason is a fear that if they studied the subject more closely they might become lip devout—that would be a pity. No man would be worse because a woman was a D.D., neither would any woman suffer because a deaconess, for example, was certified to be a person learned in Divinity.

The Dean of Durham, the Very Reverend Dr. Kitchin, is better, and everyone with whom he has been brought in contact since he arrived in the North is delighted to hear it.

Small-pox at South Shields.

The Tyne port sanitary authority has ordered proceedings to be taken against the master of the ss. *Burham* for allowing a man to leave the vessel on its arrival in the Tyne last Thursday without reporting that he was ill. The occurrence came to the knowledge of an inspector, who traced the man, found that he was suffering from small-pox, and had him promptly sent into hospital. The Tyne port sanitary authority has also determined to ask for a Government inquiry into the alleged introduction of small-pox into South Shields and the neighbouring borough of Jarrow from an admittedly infected ship, the *Regulus*. If this inquiry should be granted, as in all probability it will be, several questions of interest will arise, and among them not the least important will be the powers possessed by the medical officers to deprive sailors of their clothes for the purpose of disinfection, as to which there seems at present to be some difference of opinion.

Newcastle-upon-Tyne, May 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Opening of the Summer Session in Edinburgh.

THE summer session of the medical classes opened on Wednesday, May 1st. There was no opening address or ceremony of any kind at any of the various lecturing places in the school, with the exception of that over which Miss Jex Blake presides. She usually has a little opening and

closing ceremony. There has been an unusual number of fresh entrants at the College for Women in Chambers-street, over which the Scottish Association for the Medical Education of Women presides. At the classes generally, it is too soon to say how they are to be attended.

The Edinburgh Medico-Chirurgical Society.

This society met on Wednesday of last week; but it was evident that the holiday spirit which has pervaded the profession for the past month had not passed away. At all events the meeting was very poorly attended; in fact, the society does not appear to have recovered from the exhaustion following upon the effort it made at the time of the discussion on cardiac therapeutics. In addition to a number of interesting cases which were shown, Dr. Russell read a short paper in which he advocated draining the gall-bladder for the relief of jaundice, even when due to obstruction from malignant disease.—Dr. Leith read a long paper on an interesting case of Pulmonary Tuberculosis in which bacilli were present in quite unusual numbers, with no other signs.

Aberdeen University.

An important stage in the extension of Aberdeen University will be reached in October next, when the Mitchell Graduation Hall and Students' Union will be formally inaugurated. The event will be celebrated by interesting ceremonials and festivities prolonged over five days. On Oct. 22nd Dr. Charles Mitchell, the donor of the Graduation Hall and Students' Union, will be presented with the freedom of the city in recognition of his munificent contribution in aid of the University extension scheme. On the following day he will hand over the Students' Union Buildings, and will receive an illuminated address from the students. On Oct. 24th the Marquis of Huntly will deliver his rectorial address. On Oct. 25th Dr. Mitchell will be presented by the Senatus with an address and a gold medal, and the day being the anniversary of the death of Bishop Elphinstone, founder of the University, that prelate's memory will be honoured by a commemorative service held in Oldmachar Cathedral.

May 6th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons.

PURSUANT to the provisions of the Supplemental Charter, the election for examiners under the new regulations took place on the 7th inst., when the following Fellows of the College were elected to examine for Fellowship and on the various Courts:—In Anatomy, Dr. Burton and Dr. Myles; in Surgery, Sir Wm. Stokes and Mr. Chance; in Physiology, Dr. Coppinger and Dr. Scott; in Biology, Dr. Patteson and Dr. Scott; in Pathology, Mr. Burgess and Dr. Patteson.

Queen's College, Belfast.

In introducing Dr. Lorrain Smith, the President of Queen's College pointed out that, so far, they had only a lectureship on pathology, and having drawn attention to what had been done at Cambridge, Aberdeen, and Liverpool, he hoped that some public-spirited man would do for Belfast and the North of Ireland in the matter of pathology what Mr. R. G. Dunville and the Sorolla Trustees did for physiology, when they founded a year or two ago the Dunville Professorship in that subject. The President stated that next session, when the class in pathology would assemble, he expected it would be in the new buildings which were about to be started. The Government erect the building, but the president has been obliged to undertake to raise the funds (which, in the first instance, will mean an expenditure of £1000) for providing the requisite fittings and apparatus. It is to be hoped that Dr. Hamilton, the president of the college, who since his appointment has done so much for this institution, will have little trouble in raising the money.

The Address on Pathology at Queen's College, Belfast.

On May 1st the summer session began, and Dr. J. Lorrain Smith, who has recently been appointed lecturer, gave his introductory address on Pathology. He spoke of the increasing number of studies which students have now to undertake. The place of pathology was midway between the biological sciences and the student's strictly medical work. It thus had the function of bringing medicine into connexion with the best work in any of the biological sciences.

Dr. Lorrain Smith then dealt with the three departments of pathology—that is, morbid anatomy, experimental pathology, and bacteriology. To morbid anatomy has been given a distinctly biological form by Virchow, the founder of cellular pathology. It still is one of the most vital parts of the whole science, and is the one which could be at present taught with most profit to the student. The lecturer then referred to one or two lines of investigation in which pathology was at the present time actually profiting by the application to its problems of the most recent discoveries in regard to cell structure and cell division. Reference was made at some length to the position which experimental pathology should occupy in the science as a whole. It was, he thought, unreasonable to restrict the examination of a case of disease to the investigation of the tissues by the microscope, and especially so when those tissues had been obtained post mortem. It was the duty of the science to take up the problem from the commencement of the disease. This, by the aid of physiological methods, experimental pathology was now doing. This department of the science, however, was the most trying, and the one which required on the part of students an extensive acquaintance with physiology before they could make use of it. Dr. Lorrain Smith concluded with a short reference to bacteriology as follows: "It hardly seems necessary for me to speak of bacteriology to you, because you must all be acquainted with many of the results which have been obtained by this department of the science. The praises of it are in the mouths of everyone. It has wrought changes in medicine and surgery, in other branches of pathology, in public health, and in the management of many trades and industries. It is impossible in these days to be a good citizen without some knowledge of bacteriology. The brewing of ale is not to be trusted to anyone who is not an expert in making pure cultivations of the mixed organisms which cause fermentation. It may be that we are becoming too scientific, for it has been whispered that medicine is advancing so rapidly that it is lowering the average physical ability of the race by preserving many of those who in the barbaric ages of the past would have succumbed to all-pervading bacteria. Perhaps a more subtle criticism even than this of our too much science is that which comes from the countries of scientific ale-brewing. The men there who over their tankards remember the days before the organisms of fermentation had been isolated in pure cultivations are fain to admit that now the ale is never brewed with the wrong micro-organism; but, alas, their symposia are dulled by the monotonous uniformity of this pure cultivation product. They never reach the height of the great ales which were occasionally produced for them in the pre-scientific days, and which lent a lustre to their lives which is never to be forgotten. The popularity of the science is due, however, not only to the somewhat steady operation of its results, but also to the fact that it has enormously extended the utility of other branches of medical science. It has put in our hands the cause of many acute diseases, and enabled us to deal with them in a preventive manner. It has radically changed many methods of treatment in both surgery and medicine, and if many of its upholders are not mistaken we are about to have in serum therapeutics a method not only for the prevention of disease but also for the cure of it after the attack has begun. Every year introduces us to large and important developments of the science. For example, how much has the study and treatment of diphtheria been quickened by the recent work of Behring and Roux? Here, even if the therapeutics fail to do all that has been promised, the mere aid to diagnosis which bacteriological methods afford is certain to be of the greatest value in the work of the profession. The direct gain to the practice of medicine will yearly and yearly become greater. Even at the present day bacteriology has, by its contributions to professional knowledge, taken such a place that it is really impossible for anyone who wishes to train himself fully for his life's work to allow the opportunities for learning it to escape him. In the earlier part of this address I alluded to the feeling of oppression which the student sometimes experiences, and perhaps what I have been saying has tended in your case to increase rather than to remove it; if so, it is because what one has to say at the beginning of a course in pathology is really what would probably be much more appropriately said at the end of it. To speak of general principles without a background of detail is a habit which in science we are taught to avoid. What I have attempted to do, however, is to give you some

idea of what you ought to-day to learn from pathology if it is your wish to give it your attention. You will find that the mass of detail simplifies itself. The acquaintance with the prevailing conception of the science takes a sort of personal character, and becomes in the end an acquaintance with schools and the men who founded them."

Inspection of Rural Slaughter-houses, Belfast.

The city council at their last meeting very wisely decided to allow one or more of their officers to be appointed by the board of guardians, with a small addition to be made to their salaries, to inspect the carcasses of animals slaughtered outside the city boundary and sold for the food of man. Those slaughtered within the city are inspected by the council's officers.

Oil-lamp Accidents in Belfast.

The woman to whose case I referred in the last issue of THE LANCET has since died, this being the fifth death in connexion with lamp accidents in Belfast within seven days, four being due to explosions and one to a lamp being overturned and setting fire to the deceased's clothes. It seems that three kinds of oil are used in lamps—Scotch, Russian, and American. It is mostly through the use of American oil that explosions occur, the reason being that it has a very low flash or explosive point. In Scotch oil the flash point is 100°, in Russian oil 86°, while in American oil it is only 76°, which makes a very material difference. In America the oil could not be sold under a flash point of 100°, while in this country it can be sold at 73°. It is evident that the Select Committee appointed by the House of Commons, and which partially reported in 1894, should be reappointed to take further evidence and to report on this important question. At the inquest held on the last victim of oil-lamp explosions on May 1st, the jury added the following rider to their verdict: "That the coroner be requested to call the attention of the Parliamentary members of Belfast, Antrim, and Down to the number of fatal accidents which have taken place in this city (Belfast) and elsewhere from explosions of oil-lamps, and to request them to urge upon the Government the reappointment of the Select Committee on Petroleum, as desired by that committee, and reported to the House on the 29th April, 1894, and that legislative steps be taken at the earliest possible moment to prevent the sale of unsafe lamps and low-standard oil."

Statistics of Public Health.

I regret to say that in the table showing the births and deaths registered during the week ending April 27th there is a very high rate of mortality in Irish towns. Thus in Lurgan it was 50·2 per 1000, in Galway 52·9, while in Sligo it reached the abnormal height of 55·8. In Drogheda it was 39·5, while in Belfast, Newry, and Waterford it exceeded 32 per 1000. In the sixteen Irish towns recorded the average death-rate was 30·3 per 1000, while, on the other hand, in England and Wales the returns for the week over the thirty-three great towns in the Registrar-General's record showed that the average mortality per 1000 was only 18·9, as compared with the Irish 30·3. It is certainly a subject for consideration and reflection why the death-rate in the sixteen most considerable Irish towns should exceed that in the thirty-three English towns by something like a proportion (speaking roughly) of 11 to 7, and why in three Irish towns the death-rate per 1000 should come up to or exceed 50 per 1000—a terrible mortality.

Ulster Medical Society.

At a meeting of the Ulster Medical Society held on May 3rd, Dr. McCaw gave details of a case of Premature Labour presenting some unusual features. Mr. Kerin read notes of a series of cases of Pelvic Abscess. Dr. R. Thomson gave an account of a case of Auto-abdominal Section attended by himself and Mr. James McCullough. It seems that a woman over seventy years of age had been for some time troubled with a swelling on the left side of the abdomen, which she wished to have removed, but which was not believed to be the cause of her complaints. She was so convinced that it should be removed that she decided to do so herself. Standing over a basin she, with a pair of scissors, cut down on and removed the tumour, and, in doing so, opened the abdominal cavity and wounded part of the mesentery. When Mr. McCullough and Dr. Thomson were summoned a portion of the intestine was protruding. This they returned and carefully united the abdominal wound, and the patient made a good recovery. The tumour, which was about the size of the closed fist, was a fatty one.

and was probably in the abdominal wall, but in removing it she had opened the peritoneum. Specimens were shown at the meeting by Dr. Campbell, Dr. Thomson, and Dr. Lyness.

Dispensary Appointment.

At a meeting of the Belfast Dispensary Committee held on May 6th Dr. Robb was elected dispensary medical officer for the Springfield District (No. 9) in place of the late Dr. Jamison, whose death from typhus fever, contracted while in the discharge of his duties, I chronicled in THE LANCET of April 6th. The monthly report submitted by the medical officers showed that, owing doubtless to the improvement in the weather, the health of the inhabitants had greatly improved since the previous month.

The Cork North Infirmary.

The trustees of the North Infirmary have issued their annual report. They state that the new Gibbons Wing is nearly completed and will soon be formally opened. The late Lady Combermere was a near relative of a Dr. Gibbons, who was formerly on the staff of the hospital, and her ladyship recently bequeathed the munificent sum of £25 000 for the building of an addition to the infirmary to be called the Gibbons Wing. The trustees point out that though they have been obliged to maintain an increased number of patients during the year their subscription list is not as large as it might be. On the other hand, they were fortunate in receiving in legacies a much larger sum than usual. They are about to make an important departure with regard to the nursing of the hospital. Heretofore the hospital has been nursed by the sisters of charity, but in future the services of the sisters are to be supplemented by those of lay trained nurses and probationers. A nursing home will be established in connexion with the infirmary and nurses supplied to the general public. The medical and surgical staffs are thanked by the trustees in most graceful terms for the manner in which they discharged their duties during the year.

Poisoned by eating Mushrooms (?).

A very sad fatality has occurred in Cork. Two little boys, Denis Sheehan aged eight and John Mahony aged nine, went into the country last Wednesday with some other children for a day's amusement. About half-past four o'clock in the afternoon some fungi called "sheep's puffs" were found, and the little fellows had a general scramble for them, believing them to be mushrooms. One of the elder boys present warned his companions of the poisonous nature of the fungi and recommended them strongly not to eat them. Unfortunately his advice was not taken, and the two lads named became very ill about three hours later. Diarrhoea and vomiting set in and the two poor children died, the elder on Saturday night and the younger the following day, Sunday. An inquest was held, and a post-mortem examination revealed indications of irritant poisoning. An intelligent boy seven years old was questioned by the coroner, and in reply stated that he saw the other children eating the supposed mushrooms. He also mentioned that he himself ate "a good couple," and was unwell for the evening. All present in court were glad to see that the little chap was "alive to tell the tale."

Appointment of Professor of Modern Languages in Queen's College, Cork.

Mr. William F. T. Butler, B.A., has been appointed to the chair of Modern Languages in Queen's College, Cork. Mr. Butler is a son of Captain Butler, R.M., Cork. He was educated at the Catholic University College, Stephen's Green, Dublin, and had a most distinguished career. He graduated at the Royal University in 1891, and last year won the Travelling Studentship in Modern Literature. It is believed that his appointment to the chair in Queen's College will meet with general approbation in educational circles.

Another Boating Accident in the North.

Following closely on the disaster by which eight lives were lost by the capsizing of a boat near Mountstewart, another accident is reported to-day (the 7th inst.) by which two ladies and a gentleman were drowned. Mr. Woodhouse, of Preston, Lancashire, with his wife, son, daughter, and niece, went out yesterday from Portrush, accompanied by two boatmen. Their boat was overturned off the White Rocks, with the lamentable result which has been reported.

Payment of Medical Officers.

The Local Government Board has been forced to reconsider its decision in the case of Mr. Cahalan of Nenagh, as will be seen from the following extract from the Parliamentary

Reports for the 25th ult.: "Payment of Medical Officers.—Mr. John Morley informed Mr. William Redmond that in the case of Mr. M. J. Cahalan, medical officer to the Nenagh Board of Guardians, who had been called on to attend four urgent cases in the absence of any other medical officer, and whose fees had been stopped by the Local Government Board on the plea that over seventeen years ago he was dismissed for refusal to prosecute poor patients under the Vaccination Acts, the board had reconsidered the matter and had authorised payment for the temporary services rendered."

Limerick City Dispensary.

The recent contest for the vacant dispensary in Limerick caused considerable excitement, not only among the numerous candidates for it, but also among the applicants for the house-surgeoncy to Barrington's Hospital, which would have been rendered vacant if Mr. Mulcahy's election to the dispensary had been ratified. An objection was lodged, however, against it by the Rev. Dr. Hallanan, who stated that his name had been illegally removed from the list of the Dispensary Committee. The Local Government Board has upheld the objection and directed that a new election must take place "for a medical officer to the No. 2 Dispensary District, vacant by the resignation of Dr. Gelston." At the last election Mr. Mulcahy was victorious by 2 votes.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Alleged Cure of two cases of Cancer by Sero-therapy.

THOSE pioneers in serum therapeutics, MM. Richet and Héricourt, brought before the notice of the Académie des Sciences on the 29th ult. the encouraging results said to have been yielded by the application of this method in the treatment of malignant disease. On Feb. 9th, 1895, M. Reclus removed an osteo-sarcoma of the leg. This tumour was crushed and mixed with a little water, and the resulting liquid, after having been filtered through linen, was employed to inoculate a dorky and two dogs. The inoculation produced no reactionary symptoms; five, seven, and fourteen days respectively later the animals were bled and the serum utilised in the treatment of the two following cases. The first was a woman for whom Professor Terrier had in October, 1894, removed a growth presenting the appearance of a fibro-sarcoma, which, having attained the size of an orange since it was first noticed (eight months earlier), was adherent to the sixth, seventh, and eighth ribs, the integuments not being involved. In February, 1895, the growth had reappeared and was as large as a hazel-nut; a month later, March 7th, it had reached the volume of a small orange. Daily doses of 3 c.c. of the serum were injected during forty days into the areolar tissue surrounding the growth. The tumour began to shrink on March 25th, and the shrinkage became more and more marked as time went on. At present all that remains of the neoplasm is an indurated plaque whose contour is difficult to delimit and whose volume is less than a third of the original growth. The woman's general health has, moreover, greatly improved, and she has put on flesh to an appreciable extent. The second patient was a man aged forty-four years, admitted on March 27th, under M. Reclus, into the Pitié Hospital for a tumour of the epigastric region as large as a big orange and diagnosed as cancer of the stomach. The ideas of surgical intervention having been rejected sero-therapeutic treatment was commenced on April 6th by the injection of 4 c.c. Between that date and April 24th he had received 64 c.c. An early improvement in the general condition was noticed, the body weight having increased from 57 kilos. on April 10th to 58 kilos. on the 16th and 60 kilos. on the 23rd. From April 10th the volume of the growth had diminished, and this atrophic process continued, so that ten days later the tumour could no longer, as hitherto, be felt as a projecting isolated mass. Palpation gave only the sensation of a resisting surface—a vague thickening deeply situated and difficult to circumscribe. The extraordinary success attending the treatment in this second case leads MM. Richet and Héricourt to ask, *par un excès de prudence*, if there was not an error of diagnosis. But in Professor Terrier's case there would seem to be no reasonable doubt that a sarcoma which had recurred in the same spot was, thanks to

the injections, reduced to one-third of its original size, with manifest advantage to the general health of the patient. But I imagine most clinicians would thus early hesitate to echo the jubilant note of the discoverers who proclaim that the patient is *cured*. The growth is still present, although apparently dormant. This cautious reserve does not, however, lessen our indebtedness to those two patient workers who have done so much for sero-therapy.

Latent Tuberculosis of the Tonsils.

Professor Dieulafoy calls attention¹ to a torpid variety of pharyngeal tuberculosis the favourite seat of which is the adenoid tissue of the naso-pharynx. This tuberculosis manifests its presence by an exuberant growth of the lymphoid organs of that region—in other words, by hypertrophy of one or more of the palatine and pharyngeal tonsils. This view of Professor Dieulafoy would, if confirmed, lead us to regard hypertrophy of the tonsils and adenoid growths as, in many instances, cases of tuberculous overgrowth of adenoid tissue. He bases this belief on the results of inoculations practised on guinea-pigs of fragments of enlarged tonsils and adenoid vegetations. Of sixty animals thus inoculated with tonsil tissue, eight, or 13 per cent., succumbed to generalised tuberculosis, while of thirty-five inoculated with adenoid tissue, seven, or 20 per cent., became tuberculous. In all the persons who furnished the material for inoculation (enlarged tonsils and adenoid growths) the pharyngeal tuberculosis was primary and not consecutive to the pulmonary variety. It is to be supposed that the young subjects who have enlarged tonsils &c. provide a favourable soil for the growth of the bacillus of Koch, which finds access to the adenoid culture medium either with the food, milk especially, or with the air respired (sojourn in a bacillary atmosphere). Professor Straus of Paris has, indeed, demonstrated the presence of virulent tubercle bacilli in the nasal cavities of individuals habitually breathing the same air as phthisical patients. An open wound is not necessary for penetration, since the bacilli can find an entrance through the epithelium. In some instances the bacilli present in the adenoid tissue are, after a sojourn of months or years, destroyed by phagocytosis, which determines an indurating, fibrous process in the tonsil. In other cases, however, the bacillus finds its way into the lymphatic vessels, and enlarged submaxillary and cervical glands are the result. This lymphatic infection is often started by the occurrence of measles, scarlet fever, whooping cough, &c. This glandular tuberculosis may, in its turn, remain local, and finally end in recovery; but in other instances rapid generalisation may result. The third stage of tonsillitic tuberculosis is the spread of the process to the lungs, the bacillus reaching those organs from the cervical glands via the lymphatics, thoracic duct, and the right heart. In the course of the discussion raised by this most interesting communication M. Chauveau stated that in animals fed on tuberculous matter infection may take place by inoculation of the adenoid tissue of the base of the tongue and the isthmus of the pharynx, this inoculation being proved by the swelling of the cervical and submaxillary glands. Sometimes a minute erosion explains their inoculation, but often the surface was found intact.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Seaside Hospitals.

THE benevolent movement by which in Switzerland and Germany school-children of the less favoured classes are sent to salubrious resorts in the mountains during the holidays, so as to give them a chance of improving their condition before term begins again, has not yet its proper counterpart in Italy. If practised at all, the system has none of that all-embracing thoroughness with which (thanks in chief measure to the Empress Frederick) it has now for years been in operation north of the Alps. This much, however, Italy can justly claim, to have made an admirable beginning for the rehabilitation of rickety and scrofulous childhood by her "Ospizi Marini" (seaside hospitals). Tuscany, I believe, has the honour of initiating this movement, but nowhere in the Peninsula is it more effectively carried out than in Rome, where it has an

energetic promoter in the Minister of Public Instruction, Dr. Baccelli, whose efforts for the salvation of his country's "infanti perduti" are not the least of his many titles to honour. The office of the "Pia Opera degli Ospizi Marini" is now open for the inscription of all children duly certified as labouring under rachitis or tuberculosis, from the age (for boys) of three to twelve years, and (for girls) of three to fourteen years, whose parents are too poor to provide them *motu proprio* with the indicated seaside villeggiatura; and so all through the summer these little unfortunates of the city and province will have the benefit of the physical and moral rehabilitation wrought by continuous residence at that delightful spot on the Latin shore, Porto d'Anzio—the seat of a spacious, well-appointed, and well-administered "Ospizio Marino." If Italy, having made herself "one and independent," is anxious (in D'Azeoglio's memorable phrase) "to make Italians," she could not begin better than with her children, particularly those from whom the conditions of normal upbringing have been withheld. In this she has the sympathy and coöperation of all classes and professions, and of these latter the medical *par excellence*.

The Sanitary Services.

In my obituary notice of the lamented Professor Rinaldo Roseo¹ I omitted to mention that he had been for some time engaged in compiling a series of regulations for the better organisation and working of the hygienic and sanitary services of Rome, the basis of the said compilation being the special studies he had for some time been making on the subject. His unfinished labours were confided to his assessor, Signor Panizza, who, besides possessing great knowledge as an expert, was the deputy appointed by Parliament as "Relatore della Legge Sanitaria" (Reporter on the Sanitary Law). Signor Panizza has just completed the work delegated to him, and it has been sent up to the Giunta for consideration. It embraces all branches of public health, proceeding from the hygiene of foods and drinks, of dwelling-houses, streets, and thoroughfares, up to the "Assistenza Sanitaria," and concluding with a plan to bring the new regulations into complete harmony with the reconstituted sanitary offices and personnel. The growing needs of the Roman commune have rendered this work of hygienic reconstruction indispensable, and by the advent of next season the tourist world (that part of it which contemplates a winter's residence in the city or province) will find a new system in working order, greatly superior to what has hitherto been available either for the resident or the migratory population.

May 4th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Medical Chamber.

THE exertions of some impostors and the credulity of mankind have brought about a lowering of the dignity of the profession of medicine in Austria. The advertisements of some specialists in venereal diseases, to whom journals of repute and authority lend their space without comment, are such as to cause indignation in every self-respecting medical man. In the hope of producing some improvement the Medical Chamber at a recent meeting passed a resolution that conduct unworthy of the medical profession will be committed by whoever—(1) advertises himself in newspapers, placards, guide-books, calendars, circulars, or pamphlets, excepting advertisements in the case of commencing practice, change of address, or return after a long absence; (2) orders the publication of thanksgiving addresses by his patients; (3) recommends methods of treatment and medicines in popular publications or reports; (4) displays his address ostentatiously; and (5) pays midwives, agents, or other persons for introduction to patients.

The Medical Society.

The Medical Society has presented a petition against Paragraph 484 of the new Penal Bill, which proposes a fine of £8 in the event of failure to notify any infectious disease within the legal term. The society observes that in these cases every exertion has been made on its part to prevent the spread of infectious disease. A protest has also been published against that famous order of the Vienna magistracy, according to which medical men were obliged to

¹ Académie de Médecine, April 30th.

² THE LANCET, April 6th, 1895.

make a report on all persons treated by them for venereal or loathsome diseases—an order which has excited derision in foreign countries.

Sanitation in Austria.

Dr. Kusy, President of the Council of Hygiene, notes the progress of sanitation in Austria during 1883-93. The number of hospitals at the end of 1893 was 190, with 25 379 beds, against 162 hospitals with 19 731 beds in 1880. The number of lunatic asylums has also increased from 25 in 1883 to 29 in 1893. The number of medical men amounted to 8197 in 1893, against 7357 in 1883; and that of midwives to 17,819 in 1893, against 16,439 in 1883. The deaths referred to infectious diseases, which were 21 per cent. of all diseases in 1883, were 15 per cent. in 1893. Professor Stricker, in a critique of this report, commends the endeavours of the Council of Hygiene, but remarks that Austria has not yet obtained the complete organisation possessed by Great Britain, where even in 1873 such attention was directed to health statistics that annual reports were presented to Parliament. He referred in complimentary terms to Sir John Simon, the pioneer of English sanitary organisation.

Poisoning by Lysol.

Some two months ago a child aged three weeks, whose father had given it lysol instead of a laxative, was admitted to the Foundling Hospital suffering from paroxysms of cough and dyspnoea. The child died next day, and the post-mortem examination, made by Professor Hofmann, gave the following results. The mucous membrane of the lips was greyish and could be stripped off; the epithelium of the tongue as well as the mucous membranes of the larynx and trachea was swollen; the left lung was consolidated, violet-blue in colour, and injected with blood; the mucous membrane of the anterior part of the stomach was pale rose-coloured, whereas on the posterior part hyperæmia and intumescence were observed. Dr. Haberda, assistant to Professor Hofmann, has shown¹ that the poisonous action of lysol is due to its containing kresols. It cauterises the skin and mucous membrane, and when absorbed it affects the brain and spinal cord, producing unconsciousness, general spasms, reduction of temperature, and bleeding into the uriniferous tubules. He therefore recommends that it should be prescribed only in dilute solution.

Death of Dr. Faulhaber.

The Austrian Army Medical Staff has just sustained a heavy loss in the death of Dr. Eustach Faulhaber, Surgeon-Major and Prosecutor of the first Vienna Garrison Hospital. The deceased had been suffering for some two years from sarcomatosis, a disease which he had himself diagnosed at an early period. In spite of his terrible malady he took great interest in science, and remained until his death a true student. His principal works were: "On the Occurrence of Bacteria in the Kidney in Acute Infectious Diseases" and "The Variability of Coccus Pneumoniæ." In conjunction with Professor Weichselbaum he made important researches on the subject of Influenza.

A Monument to the late Professor Billroth.

A statue of the illustrious Billroth was unveiled in the Hospital Rudolfinerhaus on April 25th. Addresses were delivered by Count Wilozek and Dr. Gersuny, director of the Hospital, the latter observing in the course of his remarks that the profession of medicine will never forget the eminent operator, whose name is associated with every advance in surgery.

May 5th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Preventive Medicine.

At the last meeting of the Imperial Society of Medicine Professor di Giovanni of the Royal University of Padoue delivered a most interesting lecture on Preventive Medicine. His Excellency Dr. Zambaco Pasha, President of the society, introduced the distinguished visitor, who expressed his thanks for the invitation to lecture before the society. After a few introductory remarks Professor di Giovanni at once entered on his subject and spoke for three-quarters

of an hour, holding his audience in rapt attention. The following are some of the main points of the lecture: The physician has to treat the patients and not the diseases. It is therefore necessary for him to be well acquainted with each individual case, with the constitutions of each person, and with the morbid conditions which differ from each other. The lungs, the stomach, the livers of men and children, who may have the same age and apparently the same constitution, being of the same family, may differ one from the other. The tubercle bacillus is not dangerous if the subject that has absorbed it be of a robust constitution and if he passes a regular and good life. He can overcome it by his vigorous organism. Infection only occurs in those who are predisposed to it. The same is also true of certain diseases of the liver, for which this or that cause is attributed, which, however, already exists in the patient in his normal state under the form of a small hypertrophy, which has only continued to degenerate aided by the imprudence of the patient. Therefore, instead of consulting the physician when their disease has far advanced, if patients have recourse to him when the first symptoms manifest themselves, then it might be possible to mitigate predisposition, and consequently to stop the development of the disease, with a special régime, hydrotherapy, exercise, &c. At the conclusion of his highly instructive and practical lecture the Italian professor made an honourable mention of the sovereign under whose reign Turkey has seen great advancements in science.

Cholera.

The cholera has almost disappeared from Constantinople and the provinces. Not more than two or three cases are recorded weekly. The epidemic has, however, made a fresh appearance in Mecca. It will be remembered that about this time last year, when cholera appeared at Constantinople, many thought the disease was imported by the pilgrims returning from Mecca. It is gratifying to know that the Turkish Government has now very wisely sent three experts charged with the duty of disinfecting the pilgrim boats &c.

May 4th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Small-pox in Melbourne.

REFERENCE was made in a previous communication¹ to the fact that the steamer *Cloncurry* arrived at Melbourne from Calcutta with small-pox on board. The patients and crew were placed in quarantine, and the ship after thorough disinfection allowed to proceed with fresh officers and crew. After being vaccinated and their effects fumigated and disinfected the officers were released. The second officer took up his residence in a boarding house in West Melbourne and on Feb. 14th gave some linen to his landlady to send to be washed. Exactly twelve days afterwards the landlady developed small-pox. She was admitted to the Melbourne Hospital before the rash developed or the nature of the disease was recognised. As soon as the diagnosis was made the patient was sent to the sanatorium at Cut-paw-paw together with the two nurses and the resident medical officer who had been in attendance. All who had come in contact with the patient—to the number of twenty-five—were vaccinated, and the health authorities were very vigorous in taking every possible precaution against the further spread of the disease, and so far with most satisfactory results. As in some of the cases the vaccination did not appear to be successful, several persons were sent to the sanatorium—fourteen in all—but subsequently to their removal the results proved to be satisfactory.

Charge against a Medical Practitioner.

Dr. Henry Marshall Fenwick of Carlton, Victoria, was charged before the Criminal Court, first with manslaughter, and secondly with performing an illegal operation. The details of the case were given in a previous communication,² when the accused was committed for trial. The jury returned a verdict of "not guilty" in each case.

Action for Damages against a Medical Practitioner.

In the Supreme Court, Sydney, Mr. Austin N. Cooper, F.R.C.S. Irel., of Tamworth, New South Wales, had an

¹ Wiener Klinische Wochenschrift.

¹ THE LANCET, March 16th, 1895.

² THE LANCET, April 20th, 1895.

action brought against him for £2000 damages for negligent and unskilful treatment of a fractured elbow-joint. The alleged want of skill consisted in the arm having been kept in rigid splints for twelve days before passive motion was commenced. The defendant stated that he kept the splints on because the joint was too inflamed to be moved and the boy could now move his arm through an angle of 45°. Drs. MacCormack, Sydney Jones, Jamieson, and S. T. Knaggs gave evidence for Mr. Cooper and stated that there was no evidence of any malpractice or negligence. Dr. Jones had examined the arm and found good union, and that the joint could be moved over 45°. Nevertheless the jury found for the plaintiff with £200 damages.

Medical Bill for New South Wales.

For many years past efforts have been made in both the Legislative Council and the Legislative Assembly of New South Wales to pass an Act for the protection of the public and the profession against medical impostors and quacks. On March 22nd the second reading of the Medical Bill was carried in the Legislative Assembly by 52 votes to 14. During the debate on the measure Sir George Dibbs made the extraordinary statement that an irregular practitioner, who had formerly been a boatswain, boasted to him that he had made a fortune of £150,000, and that it cost him from £1700 to £2000 a year to fight the Medical Bill and prevent its being passed.

Sane or Insane: a Question of Privilege.

A law case that is almost unique has just been concluded in Melbourne after lasting several weeks, and it presents several features of medical interest. The plaintiff was Mrs. Lange, who brought an action for libel against her son-in-law, Dr. Charles Bage of South Yarra, Victoria. The alleged libels were contained in two letters which Dr. Bage wrote to the plaintiff's sister and to one of her married daughters, and in which he stated his belief that the plaintiff was not in her right mind. The defendant pleaded in addition to non-publication and privilege that he was trustee for the plaintiff under her husband's will, and that upon noticing her unusual demeanour towards her friends, her strange manner and eccentricities, and peculiar statements, he conveyed the facts, as it was his duty to do, to her sister and daughter, as they were interested in and entitled to be informed and consulted about the plaintiff's mental condition. Dr. Bage in the witness-box detailed the circumstances which led him to doubt Mrs. Lange's sanity, and read extracts from her letters, in which she said that there were machinations of the tutors and masters at Balliol College, Oxford, to prevent her son's success there, but "he is clad in armour and ready to meet all their devices to injure him." Dr. Fishbourne, a lunacy expert, gave evidence that in his opinion Mrs. Lange was suffering from "persecution mania." Several witnesses corroborated Dr. Bage's statement as to Mrs. Lange's behaviour. Then Mrs. Lange appeared in the box and point-blank denied everything said about her and explained that her written statements were not intended to be taken literally. Her son, daughter, and sister corroborated her evidence. The judge in summing up pointed out that Dr. Bage had nothing to gain by his action, that there was a point-blank contradiction in the evidence, but that Dr. Bage's statements were corroborated by written statements in many cases. Nevertheless the jury brought in a verdict for the plaintiff with damages of £750. Much sympathy is felt for Dr. Bage by the profession in Melbourne.

Annual Meeting of the Prince Alfred Hospital, Sydney.

From the reports presented to the annual meeting of the governors and subscribers to the Prince Alfred Hospital it appeared that the income for the past year amounted to £15,092, and the expenditure to £15,213. There had been a falling off in the subscriptions and donations of £392 and in the contributions from patients of £434. The statistics of the hospital showed that 2927 patients had been under treatment; 787 were cases of accident and urgency, 1043 were received under Government vouchers, and 901 contributed more or less to the cost of their maintenance. The average daily number of in-patients was 194, the rate of mortality was 9.74 per 1000, and the cost per bed was £69 13s. 3d. Attention was called to the marked increase in the number of cases of typhoid fever admitted, being 161 as against 82 the previous year.

Abdominal Surgery.

At the last meeting of the Victorian Branch of the British Medical Association Dr. M. A. O'Sullivan read some notes

on Fifty Cases of Abdominal Section. He insists on the importance in cases of salpingitis of treating the uterus as well as removing the tubes, and that it is owing to neglect of curettage and other measures before or after abdominal section, according to circumstances, that so many women remain invalided after their tubes and ovaries have been removed. He also advises that the pedicle in such cases should be freely cauterized with Paquelin's thermo-cautery to prevent infection of the peritoneum, and approves of sero-fibrous union of the incision, as advocated by Greig Smith. Eight of his cases were for fibro-myoma of the uterus, for which condition he very strongly advocates the intra-peritoneal operation, his results with which have been very satisfactory. He endorsed Lawson Tait's dictum against "tinkering" with soft cedematous myoma, and narrated a case in which he removed the ovaries for this condition, and the tumour sloughed, with a nearly fatal result.—At the same meeting Mr. R. A. Stirling read notes of a successful case of Enterectomy. The patient had a strangulated inguinal hernia for three days, and travelled 120 miles on a goods train from the country before being seen by a surgeon. The small intestine was found to be gangrenous, and four and a half inches were resected. No button or bobbin was used, but a double row of forty Lembert's sutures was inserted. The bowel was returned, but the wound was not sutured, but plugged with iodoform gauze. The patient recovered.

Hospital Appointments.

The following honorary medical officers were elected at a meeting of the board of directors of the Sydney Hospital, held on March 6th:—Physician, Dr. L. R. Huxtable (re-elected unopposed); surgeon, Dr. W. Goode (re-elected unopposed); gynaecologist, Dr. Thomas Chambers (re-elected unopposed); assistant gynaecologist, Dr. Ralph Worrall (re-elected unopposed); aural surgeon, senior, Mr. A. J. Brady (re-elected unopposed); junior, Dr. W. C. Wilkinson (re-elected); dermatologist, Dr. F. A. Bennet.—At a recent meeting of the committee of the Women's Hospital, Melbourne, Dr. A. G. Salter was elected assistant resident medical officer. There were five candidates, including a woman graduate, who was second on the poll.

Medical Defence Association of Victoria.

A Medical Defence Association has just been formed in Victoria, on the lines of the English Association, and registered as a limited liability company. Over fifty members have joined, and the following officers have been elected:—President, Dr. G. Rothwell Adam; vice-president, Mr. G. A. Syme; hon. treasurer, Dr. F. I. Owen; hon. secretary, Dr. C. E. Goodall; council, Dr. E. W. Anderson, Mr. Brett, Dr. Hamilton, Dr. Howard, Dr. Jamieson, Dr. McAdam, and Dr. Mullen.

HER ROYAL HIGHNESS THE PRINCESS OF WALES has graciously consented to open a grand bazaar in aid of St. Mary's Hospital, Paddington, at the Portman Rooms, on Thursday, June 27th next.

TRAINING OF PROBATIONERS.—The London Hospital has purchased the lease of a house in Bow-road for the preliminary training of nurses during their periods of probation before entering upon hospital work. These pupil probationers, besides being taught the practical duties of a nurse, will receive instruction in elementary physiology, anatomy, hygiene, cookery for the sick, &c., and preference will be given to applicants who are between the ages of twenty-five and thirty-five years, and who have received a good education.

ROYAL HOSPITAL FOR WOMEN AND CHILDREN.—The festival dinner in aid of the funds of this hospital was held at the Hôtel Metropole on May 4th, the Hon. W. F. D. Smith, M.P., presiding. The origin of the institution was a dispensary in Doctor's-commons, founded by Dr. Davis in 1816. In 1824 it was transferred to the Waterloo-road, and in 1875, its position in that thoroughfare being retained, the accommodation was increased to six wards containing fifty beds. Last year there were 591 in-patients and 7817 out-patients, who made upwards of 32,000 attendances. Mr. H. M. Stanley, replying to the toast of "The Visitors," emphatically expressed his admiration of the beneficent work carried out by the hospital. Donations to the amount of £1350 were announced in the course of the evening.

Obituary.

PROFESSOR CARL LUDWIG.

THE death of Professor Carl Ludwig has deprived the world not only of its greatest teacher of physiology, but of one whose labours in this department of science have been of the utmost service to practical medicine. Numerous and important as the discoveries which Ludwig and his scholars have made, the most important work of his life will nevertheless be his introduction of self-recording instruments into the domain of physiology. With characteristic generosity he was always careful to bring prominently forward the works of his predecessors, and he venerated Stephen Hales, the English country clergyman who first measured the pressure of the blood in a glass tube, as the pioneer who first estimated physiological processes quantitatively.

Ludwig's invention of recording the oscillations of blood pressure in animals by a pen swimming on the surface of a manometer was followed in a few years by the sphygmograph of Vierordt and the elaborate apparatus of Helmholtz for estimating the rate at which a stimulus travels along nerves. All the recording instruments—and they are now very numerous—by which the various movements of living beings write their own record automatically are directly descended from the kymograph of Ludwig. The great object of his life was to withdraw the phenomena of physiology from the haze of fancy and incertitude in which they were up to his time more or less enveloped, and to bring them into a line with the well-known phenomena of physics and chemistry. To this end his three friends, to whom he dedicated his Text-book of Physiology—Professor Brücke, Professor Helmholtz,

and Professor Du Bois Reymond—also worked, and the effect of the labours of this band upon physiological science it would be impossible to over-estimate. To this object Ludwig devoted the whole of a long life of tireless industry, working almost to the last with wonderful vigour. A Hessian by birth, Carl Friedrich Wilhelm Ludwig studied at Marburg and Erlangen. He graduated at Marburg in 1839 at the age of twenty-two, and after holding minor posts in that quiet university town he was appointed Professor of Comparative Anatomy in 1846. In the following year he invented the kymograph, and not only occupied himself in original researches, but initiated in the work several pupils, amongst whom may be mentioned Adolf Fick and Conrad Eckhard, now Professors of Physiology in Würzburg and Giessen respectively. The reputation he acquired caused his stay in the small town of Marburg as Professor to be short, for in 1849 he was called to the much more important position of Professor in Zürich. Hither his scholar Fick followed him, and here also he trained, amongst other distinguished pupils, Lathar Meyer (the distinguished chemist), Westphal (the neurologist), and Cloetta (Professor of Materia Medica). In 1855 he was called to a still wider sphere, and went to

Vienna as Professor in the Josephinum. Amongst his pupils here were Professors Czermak, von Becklinghausen, W. Kühne, Politzer, Leber, Stephan, Kupffer, Schwanda, Jendrassik, Setschenow, Einbrodt, Holmgren, Kowalewsky, MacGillivray, Preyer, and others, through whom his teaching was spread and his influence extended throughout Austria, Hungary, Germany, Russia, Sweden, and Holland. After ten years' work in Vienna he was called to Leipzig, where, under his direction, the Physiological Institution soon became a centre of attraction to which physiologists flocked from all parts of the world. Hither he came in April, 1865, and here in April, 1895, he died.

These thirty years were a time of steady work, hardly broken even by autumn holidays, for the annual vacation was the time chosen by professors in other universities to come to enjoy Ludwig's genial society, to see what new work he was doing, to learn from him new methods, and sometimes to make a short research under his direction. The list of those who worked with him at Leipzig is too long to quote. Amongst his English and American pupils may be mentioned in the order of time, Lauder Brunton, Coats, Bowditch, Rutherford, Moseley, Ray Lankester, Stirling, Minot,

Gaskell, Ward, Cash, Sewall, Meade Smith, Wooldridge, Walton, Buckmaster, Carslaw, F. S. Lee, F. Mall, W. H. Thompson, and Vaughan Harley. The number of his pupils altogether was considerably over two hundred, and by pupils we understand not those who had simply listened to his lectures, but men who had worked with him and been trained by him to plan out original researches for themselves as well as to perform the experiments necessary to carry them out. The patience, the kindness, the self-sacrifice he showed in the training of his pupils can hardly be imagined. Though much of the work was done by his own hand, he published it under the name of his pupils, and there is consequently a tendency to under-estimate its vast amount. It would be as impossible to enumerate his researches as to name all his pupils; all that can be done here is to indicate the general

lines of work. These were a systematic investigation of the circulation of the blood and lymph, the alterations in the composition of these fluids as they flowed through the organs and tissues of the body, the secretion of glands and excretion by the kidneys. To him and his pupils we owe most of our knowledge regarding the conditions which affect the force and frequency of the heart, the contractility of the vessels, the position of the vaso-motor centre, the distribution of blood throughout the body, and the flow of lymph. The secretion of the saliva was shown by him to occur in the several head of an animal provided the lymphatics around the glands were full so as to supply material for secretion. To his researches on the secretion of urine we owe our comprehension of why the urine is abundant in the high tension of gout, why it is scanty in mitral disease, and why the secretion becomes less copious when the gouty heart begins to fail and the arterial tension to fall. In order to study accurately the changes in the blood and lymph he devised the plan of keeping up an artificial circulation in individual organs, such as the lungs, kidneys, and liver. By this method new knowledge was also gained regarding the contractile power of the bloodvessels apart from

PROFESSOR CARL LUDWIG.

any nervous centre. The methods introduced by Ludwig into the study of physiology have also proved fruitful in pharmacology, and it is through their employment that any exact knowledge of the action of medicines on the heart and circulation which we now possess has chiefly been obtained. When we compare our present knowledge of the conditions which affect the circulation and of the means by which we can influence it with what it was when Ludwig began his work, we can guess, though we can hardly estimate exactly, how much practical medicine owes to him. His personal character was such as is very rare in any country and at any time, for to extraordinary insight and mental power he united a charm of manner, kindness, and courtesy which made all those who worked with him his life-long friends; while the example he showed of devotion to the search after truth, of self-sacrifice, and of generosity was such that they could hardly do otherwise than try to follow in his footsteps. His death will be deeply mourned all the world over, and the only consolation is that he died, as he would have wished, before his eye was so dim or his natural strength so abated that he could no longer engage in the work which was to him at once a duty and a delight.

ARTHUR EDWARD DURHAM, F.R.C.S.

THE *annus medicus* has so far been sadly remarkable for the number of deaths among leaders in medicine and surgery. Already the profession has had to lament the loss of a reigning and a past president of the Royal College of Surgeons of England, a leader in the field of State medicine has laid down his arms; and the whole scientific world is the poorer for the death of that master in physiology, Carl Ludwig. Following these comes the news of the death of one who, if not so prominently before the world as those already mentioned, was ever ready, by his skill, his sympathy, and his purse, to help the afflicted or the needy.

Arthur Edward Durham was born in 1833 at Northampton. He was not originally intended for the medical profession, and was at first employed in a bank. This occupation, however, proving distasteful to him, he entered at Guy's Hospital as a medical student when about the age of twenty—a late age in those days at which to commence. He also studied at the University of London, being a prizeman in 1854 and passing his first M.B. examination in 1857. For Mr. Hilton, whose favourite pupil he was, he did many excellent and elaborate dissections to show the nerve supply of joints. These were undertaken to illustrate the now well-known lectures on "Rest and Pain," in which Mr. Hilton alludes to his colleague's painstaking work as follows: "The first edition, in which I had the kindly and liberal help of my personal friends, Dr. Daldy and Mr. Durham, was soon out of print." Among Mr. Durham's earliest work were researches on the physiology of sleep. He trephined the skulls of dogs and inserted glass into the opening so as to reproduce, as far as possible, the physical conditions during life. Observations made after this procedure convinced him that the cortex of the brain was anemic during sleep, not congested, as had been generally supposed. The results of these researches were embodied in a paper published in the *Guy's Hospital Reports* for 1860, as was also an excellent paper on Movable Kidneys, which may still be consulted with profit. With regard to his handiwork as a surgeon he was bold, prudent, and skilful; he particularly excelled in operations for recto-vaginal fistula, harelip, lithotomy, and abdominal surgery. His remarkably long fingers, that seemed to have eyes in their tips, his flexible wrist and sinuous movements of the hand made him powerful, searching, and graceful in all his manipulations, while his invention of the lobster-tail tracheotomy-tube has proved of great value. Throughout his hospital career, whether as student, dresser, or teacher, his kindness of heart and willingness to assist others endeared him to many, while as a teacher of anatomy he was unrivalled. To his patients, whether rich or poor, he was always the same, ever unsparing of himself and his skill. Neither did he only look after his patients simply as a surgeon, but always endeavoured to give them mental comfort as well as physical by supplying them with interesting books or by helping with his purse those who their breadwinners being laid aside, would otherwise have felt the pinch of poverty. Dr. Hilton Fagge, who

was long associated with him as editor of the *Guy's Hospital Reports*, shortly before his death said to a colleague, "Durham has just been to see me. I think he is the kindest man I ever knew," and this judgment was amply justified after his premature decease. Mr. Durham was never a strong man, and for many years suffered from attacks of vomiting, the cause of which was never discovered. He was also exceedingly deaf, an affliction which was a great trouble to him, but which, so far as his private practice went, was greatly mitigated by the unselfish and never-failing labours of his brother Frederic. For several years he was subject to frequent attacks of bronchitis, which ended in considerable pulmonary emphysema. During the last winter he had more than one attack, but with his indomitable spirit was ready for work again and again. On the Saturday before his death he enjoyed a long drive with his wife and on Sunday afternoon took a walk with an old friend. That evening, however, he was very ill, and after a restless night, with much coughing and distress, was found by a colleague, who was then sent for, to have pneumonia of the right lung. During the whole of Monday his condition became more and more hopeless, and he died early on Tuesday morning (May 7th). The funeral service will be held to-day (Friday) at St. George's, Hanover-square, at 1 P.M., and a special train will leave Waterloo at 2.45 P.M. to convey the remains to Woking, when they will be cremated. Mr. Durham leaves a widow and one son, who has already made his mark in his father's profession.

Mr. Durham held the following appointments and offices:—At the Royal College of Surgeons of England he was elected as a member of the Council in 1884, and held that office at the time of his death; he was vice-president in 1892-3, but was never an examiner. At Guy's Hospital he was demonstrator of anatomy; assistant surgeon in 1861; full surgeon in 1872; and consulting surgeon in 1894. He was president of the Students' Club and used to attend nearly every meeting. He was interested in every movement connected with the welfare of students, and was always ready to take the chair at any of their meetings or to put himself to any inconvenience to be of use to them. He was president of the Clubs' Union until last year, when he retired. Guy's Hospital was the first to start a union to amalgamate the various social institutions connected with the hospital. The Students' Club is the largest constituent institution of the Union, and Mr. Durham as its president was brought into contact with every student. He was also president of the cricket club. Almost the last meeting he attended was the ordinary general meeting of the Students' Club, held on March 28th, when three hearty cheers at the end of the meeting testified to his popularity.

In addition to the literary work alluded to above he contributed articles on Intestinal Obstruction to "Quain's Dictionary of Medicine"; articles on Diseases of the Nose and the Larynx to "Holmes' System of Surgery," second edition; and, amongst others, a valuable paper in the *Transactions of the Royal Medical and Chirurgical Society* on "Section of Laryngeal Cartilages for Removal of Morbid Growths."

SIR G. BUCHANAN, M.D. LOND., LL.D. EDIN, F.R.S.

THE somewhat sudden and unexpected death of Sir George Buchanan, late medical officer to the Local Government Board, has removed from our midst one of the most distinguished leaders in that branch of medicine which has to do with the prevention of disease and the promotion of public health. Conscious of failing health, he resigned his official post early in 1892, and recently under the advice of Dr. Ringer and Mr. Pollard he underwent an operation performed by the latter. The operation was quite successful, and convalescence seemed all but established, when on Sunday morning last, the 5th inst., he suddenly expired from heart failure at the age of sixty-four. Sir George Buchanan was a student of University College, where he greatly distinguished himself, and of which body he became a Fellow in 1864. At the London University he graduated B.A. in 1864 and M.D. in 1865, having at his M.B. taken three gold medals and two scholarships. He became physician to the London Fever Hospital and to the Hospital for Sick Children, Great Ormond-street, and for many years he held the post of medical officer of health to St. Giles. It was with credentials such as these that he first commenced work in the Medical Department of the Privy Council under Sir John Simon—a chief whom he

always held in highest veneration. For eight years this work was technically occasional only, but it took up most of his time. One of his earliest inquiries was into the working of the Vaccination Laws, and he then acquired that profound belief in the protective power of that operation which he maintained to the end of his career. He also reported on typhus fever and other questions arising out of the Cotton Famine, and it was at this period of his life that, whilst studying the influence upon mortality of large works of public health that he wrote his classical reports to show how the death-rate from phthisis had been reduced in proportion to the lowering of the subsoil water by means of works of sewerage. In 1869 Sir George Buchanan permanently joined the public health service of the State, and in December, 1879, he succeeded to the post of principal medical officer formerly held by Sir John Simon and Dr. Seaton. From that date his work was mainly administrative, and it included the organisation of a Cholera Survey of the country during the European epidemic of 1884-85, which was renewed with such success in 1892-94. But the annual reports which he issued as medical officer show that he was ever at work at the scientific aspects of preventive medicine, and they abound in introductory papers from his pen which placed him in the rank of the foremost sanitarians of the world. When he resigned his official position he was still glad to work to the utmost of his ability. He had duties as a Member of the Senate of the University of London; he took an active interest in the work and welfare of the Court of Assisants of the Society of Apothecaries; he advised the Grocers' Company as to their Research Scholarships; and he served on the Royal Commission on Tuberculosis. When Lord Basing, the chairman of that Commission, died, Sir George Buchanan was asked to take his place; and at this juncture he had to decide between at once submitting to an operation to relieve the serious progress of his malady and his desire, as he himself put it, to serve the Queen as long as he could. The latter motive overcame all other considerations, and only the other day he submitted to Her Majesty the report of the Commission. This little incident is, indeed, the key to his life's history. He loved work for work's sake, and this, above all, when it tended to the welfare of others. He was never self-seeking, but he always aimed to promote the advancement and welfare of those who worked with and under him. Though the State did but little to recognise his merits, others sought to honour him as best they could. The University of Edinburgh conferred on him the honorary LL.D.; and his numerous friends established the "George Buchanan" Gold Medal of the Royal Society. It was on his retirement only that he received the honour of knighthood.

The first part of the service connected with his burial was conducted by the Rev. Llewellyn Davies at St. Martin's-in-the-Fields on Thursday, and the second part at the Brookwood Cemetery in Surrey. At one or other of these services many of his friends were present. Most of his colleagues at Whitehall, including Dr. Thorne Thorne, C.B., F.R.S., and Mr. W. H. Power, F.R.S., were present. The President of the Local Government Board was represented by his private secretary, Mr. H. C. Monro; the secretarial department and the general staff were represented; and amongst others present were Sir Anthony Home, V.C., K.C.B., and Professor Michael Foster, Secretary to the Royal Society.

CARL VOGT.

THIS distinguished German biologist died at Geneva on May 6th at the advanced age of seventy-eight. He was born at Giessen on July 5th, 1817, and was the son of Philipp Friedrich William Vogt of Bern, a well-known Swiss pharmacologist. He studied under Valentin, and early devoted himself to physiology. In 1839 he went to Neuchâtel and assisted Agassiz in various zoological researches, in particular contributing the whole of the first part of Agassiz and Desor's great work on "Freshwater Fishes of Central Europe." In addition, he wrote at this period his work "On Mountain and Glacier" (1843), "Text-book of Geology and Palaeontology" (1846), the last edition of which was published in 1879, and "Physiological Letters" (1845). In 1844 he went to Paris, where he remained for two years, then visited Italy, living at Rome and Nice, and returned to Germany in the summer of 1847. He was appointed private docent at Giessen, but the revolution of 1848 arrested his

professional career. He threw himself with ardour into the movement as a democrat, was elected Colonel of the Civic Guard of Giessen, and became a Deputy to the German National Assembly, where he distinguished himself as a brilliant orator and an untiring advocate of democratic progress. He followed Parliament on its transfer to Stuttgart, and was one of the ablest as well as one of the last supporters of the National party. He was compelled, however, to fly from Germany, and returned to Bern and Nice, where he resumed his zoological studies, the fruits of which were contained in his "Ocean and Mediterranean Sea." In 1852 he was nominated Professor of Geology at Geneva, and was subsequently appointed to the chair of Zoology in that city. He from this time identified himself with the civic life of Switzerland, becoming a member both of the Federal and National Councils. He was a voluminous writer, as, in addition to the works quoted above, he wrote "Pictures of Animal Life," "Researches upon Animal Communities," which contained much covert satire on political life; "Superstition and Science," a book advocating strong materialistic ideas and directed against the views of Wagner, "Zoological Letters," "Artificial Fish Culture," "Lectures on Useful and Noxious Animals," and many others. In 1881 he conducted a scientific expedition to the North Cape. He was one of the earliest men of standing and science in Germany to accept the views of Darwin, and was a consistent and zealous supporter of them.

GEORGE LAFFAN, M.D., M.Ch. R.U.I.,

SURGEON-MAJOR, ARMY MEDICAL STAFF.

WE regret to announce the death of Surgeon-Major Laffan, which took place on April 27th in the Presidency of Madras. He was born in county Cork in 1845, and studied medicine in Queen's College, Cork, graduating as M.D. in 1876. In the following year he entered the Army Medical Service, and became surgeon-major in 1889. Surgeon-Major Laffan took part in the Sudan Expedition of 1884-85, and in the Manipur Expedition of 1891, his services in each of these operations gaining him the award of a medal with clasp.

SAMUEL DAVIDSON, M.D. ABERD., M.R.C.S. ENG.

BY the death of Dr. Samuel Davidson of Meikle Wartle, Aberdeenshire, which took place on April 30th, our profession loses a venerable and highly respected member. The deceased gentleman, who had attained his eighty-third year and was the oldest medical practitioner in the county, having outlived most of his early contemporaries, became a Member of the Royal College of Surgeons of England as far back as 1834, and graduated as M.D. at Aberdeen in 1857. For the greater part of his life he resided at Meikle Wartle and enjoyed a considerable practice carried on throughout an extensive rural district, where he was regarded by all classes as a sound adviser and a trusty friend.

Medical News.

UNIVERSITY OF OXFORD: EXAMINATIONS IN MEDICINE AND SURGERY, TRINITY TERM, 1895.—The Regius Professor of Medicine gives notice that the following examinations will take place in Trinity Term on each day at 10 A.M.:

Final Examination for the Degree of Bachelor of Medicine.—To commence on Monday, June 10th, in the examination schools.

Examination for the Degree of Master in Surgery.—To commence on Wednesday, June 19th.

First Examination for the Degree of Bachelor of Medicine.—To commence on Friday, June 28th.

The secretary to the Board of Faculties gives notice that he will receive the names of candidates—either by letter, at any time not later than the under-mentioned days respectively, or from the candidates in person—at his office in the Clarendon-building as follows:—

1. Final Examination for the Degree of Bachelor of Medicine.—Fee £1 11s. 6d. On Saturday, May 25th, from 9.30 A.M. till 10.30 A.M.

2. Examination for the Degree of Master in Surgery.—Fee 25s. On Wednesday, June 5th, from 9.30 A.M. till 10.30 A.M.

3. *First Examination for the Degree of Bachelor of Medicine.*—On Friday, June 14th, from 9.30 a.m. till 10.30 a.m.
Fee for Organic Chemistry and Materia Medica 15s. each, and for the remaining subjects 21 11s. 6d.

Names must be transmitted or given in on one of the forms issued for that purpose. These forms can be had on application at the secretary's office. Candidates whose names have not been received at the above-mentioned times can still be admitted to examination on payment of an additional fee of two guineas, provided that their forms and fees reach the secretary at his office before noon on Thursday, June 6th, for (1); on Saturday, June 15th, for (2); and on Monday, June 24th, for (3). Candidates for the final examination must have passed the several subjects of the first examination—viz., (1) Organic Chemistry, (2) Materia Medica and Pharmacy, (3) Human Anatomy, and (4) Human Physiology; but any candidate who has obtained a first or second class in Animal Physiology in the Honour School of Natural Science is exempt from Human Physiology, and any candidate who has obtained a first or second class in Chemistry in the Honour School of Natural Science is exempt from Organic Chemistry. Candidates who passed all the examinations for the degree of B.A. before the end of Trinity Term, 1886, and who were registered as medical students on or before March 16th, 1886, are exempt from Organic Chemistry. Candidates for the examination for the degree of Master in Surgery, if they be not already members of the surgical staff of a recognised hospital, must produce a certificate countersigned by the Regius Professor of Medicine of having acted in such a hospital as dresser or house surgeon for six months. Candidates for the first examination must have passed in all the subjects of the Preliminary Examination—viz., (1) Mechanics and Physics, (2) Chemistry; (3) Animal Morphology; and (4) Botany; but any candidate who passed all the examinations for the degree of B.A. before the end of Trinity Term, 1886, or any candidate who obtained a class in Animal Morphology, or Animal Physiology, or Botany in the Honour School of Natural Science in or before Trinity Term, 1888, is exempt from Animal Morphology and Botany.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—The following candidates satisfied the examiners at the First Examination for the Degree of Bachelor in Medicine at the College of Medicine, Newcastle-upon-Tyne, in April, 1895:—

- 1.—*Elementary Anatomy and Physiology, Chemistry with Chemical Physics, and Botany with Medical Botany.*—John Robert McKinlay, Westminster Hospital; and Bertram Crossfield Stevens, St. Thomas's Hospital.
- 2.—*Anatomy and Physiology.*—Thomas Harold Gibbs, College of Medicine, Newcastle-upon-Tyne.
- 3.—*Chemistry with Chemical Physics, and Botany with Medical Botany.*—Vincent Burrow, St. Mary's Hospital; Francis Ward Crossman and Henry Reginald Ellis, St. Bartholomew's Hospital; Thomas Haylock Hulme, London Hospital; and Stanley Southam, Owens College, Manchester.
- 4.—*Botany with Medical Botany.*—Charles Henry Dickens, M.R.C.S., L.R.C.P., St. Thomas's Hospital.

The following passed under the New Regulations:—

- 1.—**ELEMENTARY ANATOMY AND BIOLOGY, CHEMISTRY, AND PHYSICS.**
Second-class Honours.—Robert Lewis Routledge and Carl Wahlgren von Bergen, College of Medicine, Newcastle-upon-Tyne.

Pass List.—Arthur Samuel Arthur, Thomas Pousford Cann, Henry Edward Davison, College of Medicine, Newcastle-upon-Tyne; Thomas Stoke Elliot, Cooke's School of Anatomy; Henry Eggleston, James Andrew Hartigan, James McConnell, College of Medicine, Newcastle-upon-Tyne; and Edgar Sheldon Wilkinson, St. Bartholomew's Hospital.

2.—ELEMENTARY ANATOMY AND BIOLOGY.

William Cowan Brown, Henry Adamson Fielden, Lawrence Fielder Heumans, Ernest Inman, Hugh Robert Kendall, Guy Brougham Picton, all of the College of Medicine, Newcastle-upon-Tyne.

3.—CHEMISTRY AND PHYSICS.

Thomas Blandford Watson, College of Medicine, Newcastle-upon-Tyne.

4.—BIOLOGY AND PHYSICS.

William Henry Isaacs Bathurst, King's College.

- 5.—**ELEMENTARY ANATOMY, CHEMISTRY, AND PHYSICS.**
Francis Gerrard Hamilton Cooke, Cooke's School of Anatomy.

The following passed the Second Examination for the degree of Bachelor in Medicine:—

ANATOMY, PHYSIOLOGY, AND MATERIA MEDICA.

Second-class Honours.—John Robert McKinlay, Francis William Rix, Westminster Hospital; and John Aston Swindle, Mason College, Birmingham.

Pass List.—Thomas George Drabble Adams, Walter Osborne Arnold, College of Medicine, Newcastle-upon-Tyne; Charles Henry Dickens, St. Thomas's Hospital; Frank Chubb Ford, St. Bartholomew's Hospital; Thomas Haylock Hulme, London Hospital; Henry

Herbert Markham, Daniel Wells Patterson, Walter Augustine Feverley, Theodore John Phillips, College of Medicine, Newcastle-upon-Tyne; Charles Seaver Smith, Mason College, Birmingham; and Robert Alfred Wilson and Thomas Woodman, College of Medicine, Newcastle-upon-Tyne.

At the Convocation held on Saturday, April 27th, the following gentlemen were recommended for the Degree of Doctor in Medicine for practitioners of fifteen years' standing, viz.:—

William Percy Ashe, L.R.C.P., M.R.C.S.; Edward Ferrand, L.R.C.P., M.R.C.S.; Stanford Harris, M.R.C.S., L.S.A.; Benjamin Jones, L.R.C.P., M.R.C.S.; Henry Arthur Latimer, M.R.C.S., L.S.A.; William Moxon, L.R.C.S. Edin., M.R.C.S.; John Taylor, L.R.C.P. Edin., L.F.P.S. Glasg.; Ebenezer Stanley Smith, M.R.C.S., L.R.C.P.; and Thomas Frederic Young, M.R.C.S., L.S.A.

The following gentlemen were recommended for the Degree of Doctor in Medicine, viz.:—

George Henry Vane Appleby, M.B., B.S. Durh.; Francis Williams Fullerton, M.B., B.S. Durh., M.R.C.S., L.R.C.P.; Reginald Green, M.B., B.S. Durh.; Walter William Hodgins, M.B., B.S. Durh., M.R.C.S., L.R.C.P.; William Harvey Mallow, M.B., B.S. Durh., F.R.C.S.; and Francis Herbert Marson, M.B., B.S. Durh., M.R.C.S., L.R.C.P.

The following gentleman was recommended for the Degree of Doctor in Hygiene, viz.:—

William Henry Turnbull, M.B., B.S., B.Hy. Durh.

The following gentleman was recommended for the Degree of Master in Surgery, viz.:—

William Martin, M.A., M.B., B.S., College of Medicine, Newcastle-upon-Tyne.

The following gentlemen were recommended for the degree of Bachelor in Medicine (M.B.), viz.:—

First-class Honours.—Charles Allan Brough, L.R.C.P. & S. Edin., College of Medicine, Newcastle-upon-Tyne.

Second-class Honours.—James Atkin Henton White, Mason College, Birmingham; John Ralph Prior, King's College; Edward Turner, St. Bartholomew's Hospital; Sidney Herbert Hawley, Mason College, Birmingham; and Harold Dickinson Senior, Charing-cross Hospital.

Pass List.—Norman Bennett, College of Medicine, Newcastle-upon-Tyne; Robert Montagu Le Hunter Couper, St. Mary's Hospital; William T'Anson Charlton; Percival Davidson, College of Medicine, Newcastle-upon-Tyne; Ernest Edward Frazer, Ernest Rowland Fothergill, Guy's Hospital; Frank Chubb Ford, M.R.C.S., St. Bartholomew's Hospital; John Reginald Fuller, St. Mary's Hospital; Edward Fielden, College of Medicine, Newcastle-upon-Tyne; Richard Withers Gilmour, St. Bartholomew's Hospital; Gilbert Gocher, Guy's Hospital; Charles Hanks, Ernest Robert Kendall, Wilfred Robert Kingdon, College of Medicine, Newcastle-upon-Tyne; George Edwyn Middlemist, London Hospital; William Harland Peake, Guy's Hospital; Marcus Sinclair Paterson, St. Mary's Hospital; Ernest Percy Satchell, Mason College, Birmingham; and George William Scott and Tom Sanderson, College of Medicine, Newcastle-upon-Tyne.

The following gentlemen were recommended for the Degree of Bachelor in Surgery (B.S.):—

Norman Bennett, William T'Anson Charlton, College of Medicine, Newcastle-upon-Tyne; Robert Montagu Le Hunter Cooper, St. Mary's Hospital; Percival Davidson, College of Medicine, Newcastle-upon-Tyne; Ernest Edward Frazer, Guy's Hospital; John Reginald Fuller, St. Mary's Hospital; Ernest Rowland Fothergill, Guy's Hospital; Edward Fielden, College of Medicine, Newcastle-upon-Tyne; Richard Withers Gilmour, St. Bartholomew's Hospital; Gilbert Gocher, Guy's Hospital; Charles Hanks, College of Medicine, Newcastle-upon-Tyne; William Harland Peake, Guy's Hospital; Marcus Sinclair Paterson, St. Mary's Hospital; John Ralph Prior, King's College; Ernest Percy Satchell, Mason College, Birmingham; George William Scott, Tom Sanderson, College of Medicine, Newcastle-upon-Tyne; Edward Turner, St. Bartholomew's Hospital; and James Atkin Henton White, Mason College, Birmingham.

The following gentlemen were recommended for the Degree of Bachelor in Hygiene:—

George John Atburn, M.B., M.S. Edin.; George Henry Vane Appleby, M.B., B.S. Durh.; Edward Turner, M.R.C.S., L.R.C.P.; and Edward Cecil Willcox, M.B., B.S. Durh.

And the following gentleman was recommended for the Diploma in Public Health (D.P.H.):—

William Henry Symons, L.S.A.

FOREIGN UNIVERSITY INTELLIGENCE.—*Cracow:* Dr. Alexander Rosner has been recognised as *privat-docent* in Obstetrics.—*Gratz:* Dr. Adolf Tarisch has been promoted to an Ordinary Professorship of Dermatology.—*Prague:* Dr. Eduard Nessel, dental surgeon, has been promoted to an Extraordinary Professorship in the University of Bohemia.—*Vienna:* Dr. Norbert Ortner has been recognised as *privat-docent* in Medical Pathology. Dr. Leopold Réti has been recognised as *privat-docent* in Laryngology.

ABERDEEN UNIVERSITY CLUB, LONDON.—The May dinner of this club will be held at the Holborn Restaurant on Wednesday, the 15th inst., at 7.30 P.M., when the Rev. Donald MacLeod, D.D., will occupy the chair.

THE Local Government Board has confirmed the appointment of Mr. F. J. Brown of Newark as medical officer and public vaccinator for the Caunton and Elston districts of the Southwell Union, at a salary of £32 a year. As Mr. Brown does not reside within these districts the appointment is sanctioned for one year only, and must be annually confirmed.

OXFORD MEDICAL SOCIETY.—A special meeting will be held in the anatomical lecture theatre on Friday, May 17th, at 8.30 P.M. Dr. Sidney Martin will read a paper on the Pathological Results of the Royal Commission on Tuberculosis. The President of the society, Professor Bardon Sanderson, one of the Commissioners, will take part in the discussion. Visitors will be welcomed.

ROYAL VISIT TO THE CHELSEA HOSPITAL FOR WOMEN.—Her Royal Highness the Princess Mary Adelaide, Duchess of Teck, has graciously consented to visit the Chelsea Hospital for Women on Wednesday, May 22nd, at 4 P.M., when her Royal Highness will open and name the "Mary Adelaide" Ward, and also receive purses of money from ladies who are willing to aid this institution. Purses may be obtained from the Secretary, at the hospital.

THE Charity Record announces the following complete list of Baron de Hirsch's benefactions to hospitals &c., for 1895:—

Queen Charlotte Lying-in ...	£200	British Home for Incurables ...	£300
Bethnal Green ...	200	Brompton Consumption ...	500
Charing Cross ...	500	St. Mary's ...	300
Evelina ...	200	North-Eastern ...	300
North-West London ...	500	Cancer (Free) ...	200
Westminster ...	300	Jewish Convalescent ...	200
St. Andrew's Convalescent ...	200	King's College Hospital ...	300
Home ...	200	Middlesex ...	300
Poplar ...	200	Great Ormond-street ...	100
Princess Mary Village Homes ...	100		
Metropolitan Convalescent Institution ...	100		£5000

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Opium Commission.

SIR JOSEPH PEASE has given notice that on Friday, May 24th, he will call attention to the Report of the Royal Commission on Opium, and move: "that this House, having had before it its resolution of June 30th, 1893, pressing on the Government of India to continue their policy of greatly diminishing the cultivation of the poppy and the production and sale of opium, and having had presented to it the Report of the Royal Commission, appointed Sept. 2nd, 1893, to inquire into various matters connected with the cultivation of the poppy in India, is of opinion that the system by which the Indian Opium revenue is raised is morally indefensible, and would urge upon the Indian Government that they should cease to grant licenses for the cultivation of the poppy and sale of opium in British India, except to supply the legitimate demand for medical purposes, and that they should at the same time take measures to arrest the transit of Malwa opium through British territory."

Factories and Workshops Bill.

The Factories and Workshops Bill is now being considered by the Grand Committee of the House of Commons on Trade, but so far very few amendments have been made in the measure. On Tuesday, May 7th, there was an important debate in connexion with the clause which provides a penalty for the employment of persons in places injurious to health. Mr. William Allen proposed an amendment making it obligatory on the occupiers of factories and workshops to obtain a license every year from the inspector of the district. Mr. Buxton, on behalf of the Government, expressed sympathy with the object of the amendment, but said the apathy of many local sanitary authorities was notorious, and they could not leave this important matter in their hands. He added, however, that with regard to new premises the Government are going to propose some form of licence or certificate. Mr. Asquith spoke in the same line. What, he asked, would be the use of inspecting these places at the beginning of the year unless their sanitary condition were afterwards kept under constant observation? Several members took the view that the amendment would interfere with cottage industries in rural districts and drive trade into the hands of the large factory owners in towns. In the end the amendment was defeated by a large majority.

The Midwives Registration Bill.

This Bill, which has been introduced into the House of Lords, con-

sists of eighteen clauses. The text of the Bill is printed in full in another column.

HOUSE OF COMMONS.

THURSDAY, MAY 2ND.

The Operation of the Merchandise Marks Act.

Mr. Bryce, President of the Local Government Board, answering a question on this subject put by Mr. Brookfield for Colonel Howard Vincent, said that ten summonses in all have been issued under the Act since Jan. 1st, 1894, and in all of these convictions had been obtained. Other cases were also submitted to the Solicitor for his opinion as to proceedings, but as to some he advised that they did not come within the Act, and in other cases there was not evidence to secure a conviction.

The Veterinary College for Ireland.

Mr. John Morley, in reply to Mr. Johnston, said it is the intention of the Government to bring in a Bill to make certain provision in connexion with the proposed Veterinary College for Ireland, an institution which, in the opinion of the Government, will be of considerable educational advantage. The provision will not be for the endowment of the college, but merely a grant of a lump sum in aid towards the acquisition of buildings and fittings. The grant will not reduce the annual sum paid to the Intermediate Education Board as their share of the local taxation duties, but will be withdrawn from an accumulation in their hands in respect of their share in these duties not expended by them in former years.

Weather Forecasts for Agriculturists.

Mr. Herbert Gardner, President of the Board of Agriculture, said, in answer to Mr. Strachey, that so far as he could gather from the information which had reached him the experimental exhibition of the weather forecasts at the telegraph offices in rural districts has not been so beneficial as he had hoped, and he was doubtful whether the assistance rendered to agriculturists is sufficient to justify him in making a further application to the Treasury on the subject. He should be glad, however, to further consider the matter, and if it should appear that the arrangement is of real service to agriculturists during harvest time he would do his best to secure its continuance in localities where it is appreciated.

The Budget.

The Chancellor of the Exchequer at this sitting of the House made his annual statement as to the finances of the country. The only changes in taxation he proposed were the withdrawal of the extra 6d. per gallon duty on spirits and the reimposition for another year of the extra 6d. per barrel on beer. In the course of his statement Sir William Harcourt made some interesting references to the food and drink of the year. With regard to tea, he said that the duty had yielded £3,587,000, or £34,000 more than in the year 1893-94. This increase represented in quantity 5,650,000 lb., and in ratio 2.6 per cent., this percentage being a good deal more than twice as great as the increase of the population. The teas of India and Ceylon now constitute 86 per cent. of the whole, whilst in 1894 they constituted only 3 per cent. of the consumption. The yield of tobacco in the past year had been £10,416,000, or £96,000 more than in 1893-94. This increase, Sir William Harcourt said, was probably not to be taken as a normal figure, as the consumption in the latter year was no doubt depressed by the long-continued coal strike and other circumstances of depression, which made the tobacco revenue practically stagnant; but it would be found that the average annual increase over seven years had been nearly 3 per cent. per annum, which was about three times as great as the increase of population. The consumption of coffee had been steadily decreasing. In 1885-86 the revenue from it was £205,000; last year it was only £170,000. Cocoa, on the other hand, was steadily growing in consumption. In the last year there had been an increase of 3,383,000 lb., as compared with 1893-94, and an improvement of £14,000 in the revenue. Dried fruits showed an increase of £20,000 beyond the figure of the preceding year. Turning to another class of commodities, Sir William Harcourt said that, as he had indicated on several former occasions, the consumption of wine was constantly on the decrease. The receipt in 1894-95 was £1,144,000, as against £1,210,000 in 1893-94. Since 1875 the quantity had fallen from 17,200,000 gallons to 13,830,000, and in the last year the fall was 250,000 gallons. The quantity of sparkling wine, which stood at 825,000 dozens in 1890, had fallen to 650,000 dozens in the last year. The produce of the duty on spirits had been £4,197,000, or £67,000 in excess of 1893-94. For the first three quarters up to Dec. 31st there had been no increase on the previous year, and it would seem that if things had gone on in their ordinary course, in spite of the extra sixpence, there would have been little or no increase of revenue, but owing to the extraordinary severity of the weather in February the receipts from rum rose suddenly to an excess of £100,000. Brandy fell £91,000 below the yield of 1893-94. The taste for this drink was evidently on the decline, for in fifteen years the quantity had diminished by 1,000,000 gallons, or 31 per cent., while the population had increased 13 per cent. An examination of the increased and increasing consumption of non-dutiable articles—such as meat, eggs, sugar, butter, and cheese; fruit, such as apples, oranges, and lemons; fuel, as coal; light, as petroleum—showed from year to year, and markedly last year, an increase in the average consumption of these articles. There was one article which was perhaps a greater test than any other, and that was meat. In the three years 1882 to 1884 the consumption of meat was 108 lb. per head; and in the three years 1891 to 1893 the consumption was 119 lb. per head, or an increase of 10 per cent. The consumption of foreign and home-grown meat in these latter three years was the largest that ever took place, and the increase in the consumption of an article like meat was a significant indication of the well-being of the people. To sum up, Sir William Harcourt said that the figures went to show that the mass of the people had in the past year, and in many years past, been able to obtain, and had enjoyed, still larger quantities of the necessaries and comforts of life at lower prices.

MONDAY, MAY 6TH.

Quarantine in South America.

Sir Edward Grey, in the course of a reply, said that the South American Republics had been approached on the subject of their quarantine

regulations, but none of them had as yet expressed themselves willing to adopt the principles of the Dresden Sanitary Convention. Mr. Phipps, Her Majesty's Minister at Rio de Janeiro, was specially instructed on proceeding to his post to make earnest efforts for improvement in the quarantine arrangements in Brazil, and a conference was now sitting at Rio de Janeiro to consider the question. It was understood that the Brazilian Government had promised to provide three fresh quarantine stations, besides some other reforms in their regulations.

Treatment of Fever Patients in London.

Mr. Bartley asked the President of the Local Government Board whether his attention had been drawn to a report, dated April 8th last, from the medical officer of health of Islington concerning the premature discharge of fever patients from the Metropolitan Asylums Board's hospitals; and whether he would allay public anxiety on the subject by appointing a committee to inquire into the question?—Mr. Shaw-Lefevre replied: I have communicated with the Metropolitan Asylums managers with respect to the report mentioned in the question, and I am informed that they have referred to their General Purposes Committee for consideration and report, not only concerning this particular report, but also the whole question raised in the annual report for 1894 of the medical superintendent of the North-Eastern Hospital as to the outbreak of illness in households after the return from hospital of recovered patients. Allegations have been made as to similar outbreaks where patients have been discharged from the hospitals of other bodies, and the subject has recently received the attention of the Medical Department of the Local Government Board, who hope shortly to issue a report with respect to it.

The Water-supply at Aldershot.

Mr. Campbell-Bannerman, in answer to a question, said that the water-supply to the new barracks at Aldershot had been recently investigated and the water had been analysed by the Professor of Military Hygiene at Netley. The steps to be taken on that report were now under consideration. It was not usual to publish such a report.

Accidents in Coal Mines.

Mr. Asquith, replying to Sir James Fergusson, said that the total number of persons injured in coal mines during 1894, as reported under Section 35 of the Coal Mines' Regulation Act of 1887, was 4081. In future this information would be published in the summary of statistics of mines and minerals.

TUESDAY, MAY 7TH.

London University Bill.

Mr. Acland intimated that this Bill would be introduced in the House of Lords on Thursday, May 9th.

The Meat-supply for the Army.

A number of questions on this subject were addressed to the Financial Secretary to the War Office, and in the course of his replies Mr. Woodall said that the contractor was required to deliver at least 40 per cent. of the meat from home-killed supplies. Foreign supplies of beef were only available between October and the end of May, and during the rest of the year the beef supplied must be home grown. As to mutton, it was only allowed on one day in the week, and it might either be refrigerated or home grown. The quality of the meat was found every year to be more satisfactory.

WEDNESDAY, MAY 8TH.

Cremation.

Sir Thomas Roe introduced a Bill to empower burial boards and local authorities to provide for cremation.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on the Adulteration of Food Products resumed the examination of witnesses on Tuesday, May 7th, Sir Walter Foster occupying the chair.

Mr. Trengrouse, a member of the Produce Exchange and the London Chamber of Commerce, gave evidence with regard to tilled or imitation cheese. He would not say that it was absolutely without nutritive properties, but he certainly would not care to eat it himself. He had been offered a liberal commission to sell it but had refused, being of opinion that it was an article of commerce by which the public were defrauded. Its manufacture and importation should, in his opinion, be suppressed, and he would go so far as to inflict imprisonment on the occasion of a third conviction. Lard was imported in large quantities from America. Generally speaking, it was pure, but adulteration was practised by the introduction of cotton-seed oil, stearine, and beef fat.

Mr. Henry Lane, another member of the London Chamber of Commerce, went at length into the lard question. He expressed the opinion that adulteration does not go on now to anything like the extent it used to do, and he advocated strict scrutiny and the imposition of substantial fines.

Mr. J. M. Harris, from Calne, said it was possible to get from English, Scotch, and Irish pigs a lard which was as solid as butter; but in the case of American pigs, which were fed chiefly on Indian corn, the lard was not so solid, and foreign fat was introduced into it on the plea of stiffening. He believed that a great quantity of raw material brought from America was treated in this country and sold as home-grown. In this connexion he cited lard and bacon.

The Committee then adjourned.

The Committee met again on the following day, with Sir Walter Foster in the chair.

Mr. Alexander Osborne, of Messrs. Osborne and Sons, wholesale provision merchants, Glasgow, gave evidence with regard to butter and cheese. His chief recommendation was that foreign Governments should be invited to give a guarantee with the butter and cheese coming from their respective countries and put a brand upon them, and that if they declined to do this in this country should not allow the articles to be imported. He detested the practice which prevails in some parts of Scotland of making cheese from skim milk and oleo, saying that a perfectly good and wholesome article was produced. He gave the results of analysis of samples of Dunlop cheese, which is the kind mainly made in Scotland—this oleo cheese, and Gorgonzola. In the matter of

butter fat the Dunlop cheese contained 31.68 per cent., the oleo 11.32, and the Gorgonzola 26.99 per cent.; other fat Dunlop nothing, oleo 16.98, and Gorgonzola 6.75 per cent.; casein Dunlop 32.30 per cent., oleo 32.64, and Gorgonzola 26.18 per cent.

Mr. Fry was examined as to the trade in cocoa. He claimed that the introduction of sugar and arrowroot to increase the solubility of the article could not be regarded as adulteration in any sense. He did not see any great objection to the proportions being stated on the label, although he thought it hardly fair to the manufacturer that he should be called upon to make the disclosure. As to the arrowroot, it would not be right to describe it as starch, because it would prejudice the article in the mind of the public. It would be as fair to call arrowroot in cocoa starch as it would be to call gelatine used in blanc mange glue. As to the term "cocoa," it ought to be borne in mind that the present mixtures were on the market many years before pure cocoa was heard of.

Mr. Hahnemann Epps, director of James Epps and Co., Limited, and chairman of the Cocoa Subsection of the London Chamber of Commerce, was next examined. He explained at some length the processes for the preparation of cocoa. The nibs, he said, were ground to a paste, and then one of three methods was employed to subdivide and incorporate or to regulate the constituents of the cocoa, particularly the fat, of which there was usually 50 per cent. present in the nibs. The oldest method was that of adding sugar and arrowroot; another method was to remove a large proportion of the fat; and the third was in addition to treat the cocoa chemically with potash, soda, or ammonia. For different classes of people, varying as they did in their wants and tastes, the first two methods were suitable and were appreciated. The third method by chemical treatment seemed to him to be objectionable. The native character of the cocoa with the aroma and colour was destroyed, and it was stated by Dr. Sidney Ringer of Oxford University and the German chemist Moeller that the added alkalis directly hindered digestion and impaired the nutrition of the body. His firm had considered the matter on many occasions and had deliberately refused to employ either of the alkali processes. It would, in his opinion, be unwise to place restrictions on the supply of good preparations of cocoa which retained the constituents of cocoa intact, which were economical in use, and to which the people were accustomed. It was well known that in the Royal Navy since 1822 the sailors and marines, numbering now 70,000, had been daily supplied with Government-made prepared cocoa, composed of about 50 per cent. cocoa and 50 per cent. of sugar and arrowroot, and Admiral Field had lately given his opinion that such a diet for hard-working men could not be improved upon. As cocoa was very rich with fat, which, if left free, would float in great drops on the surface, the manufacturer had to consider what was the actual quantity of sugar and arrowroot required to incorporate with the cocoa and furnish readily a smooth and agreeable drink. His firm declared on their labels the ingredients used in the preparation of cocoa.

The Committee adjourned for a week.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

- ADCOCK, G. R., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer for the Home Union.
- BAKEWELL, R. TURIK, M.B., M.R.C.S., has been appointed Anaesthetist to the Hospital for Sick Children, Great Ormond-street.
- BLAKISTON, A. A., M.R.C.S., has been reappointed Medical Officer of Health for the Borough of Glastonbury.
- BODEN, J. S., M.R.C.S., L.R.C.P., has been appointed House Accoucheur to King's College Hospital.
- BOND, N. TROUGHTON, M.B., C.M. Edin., has been appointed Medical Officer for the No. 5 District of the Liskeard Union.
- BUNSFIELD, A., B.A. Cantab., B.Sc. Lond., M.R.C.S., L.R.C.P., has been appointed Assistant House Physician to King's College Hospital.
- BURRIDGE, H. A., M.R.C.S., L.R.C.P., has been appointed Assistant House Accoucheur to King's College Hospital.
- BURY, EDWARD C., M.D. St. And., M.R.C.S., has been appointed Medical Officer of Health to the Wisbech District Council.
- CLAY, J., M.D. Durh., B.S., has been appointed House Surgeon to the Radcliffe Infirmary, Oxford.
- COUNSELLER, W. P., M.D. Durh., L.R.C.P., L.M. Irel., M.R.C.S., has been appointed Medical Officer of Health to the Clitheroe Rural District Council.
- COX, WM., M.R.C.S., has been appointed Medical Officer of Health for the Winchcombe Rural District Council.
- CRAWFORD, RAYMOND, M.A., M.B., B.Ch. Oxon., M.R.C.P. Lond., has been appointed House Physician to King's College Hospital.
- DATK, WM. H., M.R.C.S., has been appointed Medical Officer of Health to the Wellington Rural District Council.
- DAVIES, J., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Medical Officer to the Holborn Union Schools at Mitcham.
- EDMONDS, F., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Chesterfield Sanitary District and the Workhouse of the Chesterfield Union.
- ELLIOT, J., M.R.C.S., has been appointed Medical Officer of Health to the Erith District Council.
- ESSOR, HY. C., M.R.C.S., has been appointed Honorary Ophthalmic Surgeon to the Newport and Monmouthshire Infirmary.
- EVERS, CHAS. J., M.D. Durh., M.R.C.S. Eng., has been reappointed Medical Officer of Health for the Faversham Borough and Port Sanitary Authority.
- FLOWER, FRED., M.R.C.S., has been appointed Medical Officer of Health to the Warminster District Council.

GOODFELLOW, JAS. A., M.B., C.M. Glas., has been appointed Medical Officer of Health to the Brampton Rural District Council.

JONES, J. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Borough of Aberavon.

KEMPTHORNE, A. E., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District of the Parish of St. Matthew, Bethnal-green.

LEAF, CREIL HUNTINGTON, M.A., M.B., B.C. Camb., M.R.C.S., has been appointed Assistant Demonstrator in Anatomy at the London Hospital.

MACKINTOSH, A., M.D., L.F.P.S., L.M. Glas. has been appointed Medical Officer of Health to the Chesterfield Rural District Council, and also to the Urban District Councils of Clay Cross and Dronfield.

MOSSMAN, R. A., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Milton Sanitary District of the Sculcoates Union, vice Jackson, resigned.

MOSSOP, A. GEOR., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Medical Officer of Health to the Newhaven Urban District Council.

NETTLE, WM., M.R.C.S., has been reappointed Medical Officer of Health to the Liskeard Town Council.

OLIVER, GEORGE H., M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., has been appointed Assistant Surgeon to the Bradford Eye and Ear Hospital, vice G. H. Dodd, resigned.

OLVER, R. S., M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.

PALMER, A. M., L.R.C.P., L.M. Edin., M.R.C.S., has been appointed Medical Officer of Health to the Whittington Urban District Council.

PENNY, F. S., M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.

PERCIVAL, THOMAS, M.R.C.S., L.M., has been appointed Medical Officer of Health to the Pontefract Rural District Council.

REES, DAVID V., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Brecon Urban Sanitary District.

RICE, T. E., L.S.A. Lond., has been appointed House Surgeon to King's College Hospital.

ROBB, A. GARDNER, M.B., B.Ch. Irel., has been appointed Government Medical Officer, Public Vaccinator, and Medical Officer of Health for the Springfield District of Belfast.

ROBERTS, G. A. E., M.R.C.S., has been appointed Medical Officer of Health to the Winchester District Council.

SHIPPARD, AMY, M.B. Lond., has been appointed Assistant Ophthalmic Surgeon to the New Hospital for Women, Euston-road.

SMITH, G. A., M.R.C.S., L.R.C.P., has been appointed Ophthalmic Clinical Assistant to King's College Hospital.

SOUTHEY, A. J., M.R.C.S., has been appointed a District Medical Officer to the Eton Urban District Council.

THOMSON, D. G. P., M.B., M.S. Edin., has been appointed Medical Officer of Health to the Penrith District Council.

WATSON, WM., M.R.C.S., has been reappointed Medical Officer of Health to the Rochester Urban and Port Sanitary Authorities.

WEBB, WM. H., M.D. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health to the Kingsbridge Rural District Council.

WILLS, THOMAS MUNN, F.R.C.S. Irel., J.P., Senior Honorary Surgeon, has been appointed Consulting Surgeon to the Bootle Borough Hospital, Liverpool.

YOUNG, T. BART, M.D. Brux., M.R.C.S. Eng., L.R.C.P. and S. Edin., has been appointed Medical Officer of Health to the Halesowen Rural District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASYLUM FOR IDIOTS, Earlswood, Redhill, Surrey.—Assistant Medical Officer. Salary £150 a year, with board and residence. Applications to the Secretary, 36, King William-street, London-bridge, E.C.

BLACKBURN AND EAST LANCASHIRE INFIRMARY, Blackburn.—Junior House Surgeon. Salary £50 per annum, with board, washing, lodging, &c.

BOROUGH OF STOCKTON-ON-TEES.—Medical Officer of Health and Medical Superintendent of the Fever Hospital. Salary £300 per annum. Applications to the Town Clerk.

CARDIFF INFIRMARY.—Senior Resident Medical Officer for one year. Salary £100 a year, with washing and furnished apartments.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer to act as Locum Tenens for about three months during the summer. Salary £22s. per month, with board, lodging, &c.

DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

DORSET COUNTY HOSPITAL, Dorchester.—House Surgeon, unmarried. Salary £70. To reside and board in the Hospital.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glais-road, E.—Assistant Physician for Out-patients.

EAST SUFFOLK AND IPSWICH HOSPITAL, Ipswich.—Second House Surgeon, unmarried. Salary £70 per annum, with board, lodging, and washing.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Pathologist and Registrar for one year. Honorarium 50 guineas per annum.

GUARDIANS OF KENSINGTON.—Second Assistant Resident Medical Officer for the Workhouse and Infirmary. Salary £30 per annum, with apartments, board, and washing. Applications to the Clerk to the Guardians, Marlborough-road, Kensington, W.

HALLIFAX INFIRMARY AND DISPENSARY.—House Surgeon, unmarried. Salary £30 per annum, advancing £10 per annum up to £100, with residence, board, and washing.

MANCHESTER SOUTHERN AND MATERNITY HOSPITAL.—Resident House Surgeon. Honorarium at the rate of £50 per annum and board.

NEW HOSPITAL FOR WOMEN, Euston-road, London.—Medical Women as House Surgeons.

ROTHERHAM HOSPITAL AND DISPENSARY.—Resident House Surgeon for three years. Salary £100 per annum, with rooms, washing, and commons (exclusive of alcoholic drinks).

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—House Physician, for six months. Salary at the rate of £70 per annum, with board and lodging.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—Clinical Assistants for six months.

ST. LUKE'S HOSPITAL, London, E.C.—Clinical Assistant for six months. Board and residence provided.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Assistant House Surgeon for six months. Board, washing, and lodging in the Institution provided.

WEST RIDING ASYLUM, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £100 per annum, rising £10 a year up to £150, with board &c.

WESTERN GENERAL DISPENSARY, Marylebone-road, London.—Junior House Surgeon, unmarried. Salary £50 per annum, with rooms and board.

WORCESTER GENERAL INFIRMARY.—Assistant House Surgeon and Dispenser for two years, unmarried. Salary £70 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS.

COWLEY.—On May 2nd, at Willow Bank, Upton-on-Severn, the wife of J. Selwyn Cowley, M.R.C.S. Eng., &c., of a son.

CUTHFIELD.—On May 3rd, at Merton House, Ross, Herefordshire, the wife of Arthur Cuthfield, B.A., B.Sc., M.R.C.S., of a son.

GODFREY.—On May 4th, at Inglenook, Stockton-on-Tees, the wife of T. H. Godfrey, Esq., M.B., of a daughter.

HURRY.—On May 5th, at Abbotsbrook, Reading, the wife of Dr. Jamieson B. Hurry, M.A. Cantab., of a daughter.

MACGILLIVRAY.—On May 5th, at Rutland-street, Edinburgh, the wife of Charles Watson Macgillivray, M.D., F.R.C.S. Edin., of a son.

MINTER.—On May 6th, at Nelson-street, Rotherham, Yorks, the wife of J. L. Minter, M.D., M.R.C.S., of a daughter.

SLAUGHTER.—On May 5th, at Darwen Bank, Darwen, the wife of Ernest A. Slaughter, B.A., M.D., of Brondesbury-road, Kilburn, N.W., of a son.

WALLER.—On May 3rd, at Thorneybrook, Chelmsford, the wife of T. H. Waller, M.R.C.S., L.R.C.P. Lond., of a daughter.

MARRIAGES.

JOHNSTON—GAINSFORD.—On May 2nd, at St. Saviour's, Hitchin, Alexander J. J. Johnston, Staff-Surgeon Royal Navy, H.M.S. Blenheim, son of the late J. Wingate Johnston, M.D., R.N., to Hilba Margaret, daughter of the Rev. George Gainsford.

MCCARTHY—LEGGATT.—On April 30th, at St. John Baptist Church, Holland-road, W., James Desmond McCarthy, C.M.G., M.D., late Surgeon R.N., and P.M.O. in H.M. Colonial Service, retired, to Clara Augusta, eldest daughter of the late Horatio Bethune Leggatt, Brownhich, Hants.

SUTTON—WOLFE.—On April 30th, at Christ Church, Woburn-square, by the Rev. Henry Carter, M.A., of Forty-hill, Enfield, assisted by the Rev. J. J. Glendinning Nash, M.A., incumbent, Charles Robert Arnold Sutton, M.A., M.D. Cantab., of Sidcup, younger son of R. C. Sutton of Carisbrooke House, Forest-grove, Nottingham, to Charlotte Amelia, eldest daughter of James W. Wolfe, of 20, Russell-square, W.C., and Oakfield, Herts.

TODD—DECKERS.—On April 27th, at Bromley, Kent, Frederick Todd, M.R.C.S., L.D.S., of Finsbury-circus, to Alphonsine, elder daughter of the late Alphonse Deckers, of Amhurst-road, N.E.

YEOMAN—FERGUSON.—On April 30th, at St. Peter's, Heston, Cheshire, Dr. Christopher William Yeoman, eldest son of A. R. Yeoman, Esq., M.A., Inspector's Department, Somerset House, London, to Ida Isabel (Idabelle), youngest daughter of the late James Fergusson, Esq., of Liverpool.

DEATHS.

BUCHANAN.—On May 5th, Sir George Buchanan, LL.D., M.D., F.R.S., of Woburn-square, W.C., formerly Medical Officer of H.M.'s Local Government Board, aged 64.

BUTTERFIELD.—On May 1st, at his residence, Greystone, Sevenoaks, Harris Butterfield, M.R.C.S., L.S.A., Medical Officer of Health for West Kent.

CARTER.—On May 4th, at Budleigh Salterton, Henry John Carter, F.R.S., retired Surgeon-Major Bombay Army, aged 82.

DURHAM.—On May 7th, at 82, Brook street, Grosvenor-square, Arthur Edward Durham, F.R.C.S., Consulting Surgeon to Guy's Hospital, member of the Council of the Royal College of Surgeons, in his 62nd year. No flowers by request. The funeral service will be held at St. George's Church, Hanover-square, at one o'clock p.m. on Friday, May 10th. Funeral at the Crematorium, Woking; train leaving Necropolis-station, L. and S.W.R., Westminster-bridge-road, at half-past two.

HARPER.—On May 3rd, at Abingdon-road, Kensington, W., Henry Harper, Deputy-Surgeon-General Madras Medical Service (Retired).

MOORHEAD.—On May 6th, at Margate, Edward Moorhead, M.D., Deputy-Inspector-General (Retired) Army Medical Department, aged 75 years.

SPACKMAN.—On May 5th, at Faringdon, Berks., Frederick Charles Spackman, M.R.C.S., L.S.A., aged 69 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—MEDICAL SOCIETY OF LONDON.—8 P.M. General Meeting for the Election of Officers and Council. 8.30 P.M. Ordinary Meeting. Mr. C. B. Lockwood: The Diagnosis of Retro-peritoneal Sarcoma, with cases.

TUESDAY.—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Adjourned Discussion on Dr. Felix Semon's paper on "The Probable Pathological Identity of the Various Forms of Acute Septic Inflammations of the Throat and Neck, hitherto described as Acute (Edema of the Larynx, Cleftomatous Laryngitis, Erysipelas of the Pharynx and Larynx, Phlegmon of the Pharynx and Larynx, and Angina Ludovici."

LONDON VEGETARIAN SOCIETY.—8 P.M. Public Meeting on Slaughtering, to be held in the Board Room, Memorial Hall, Farringdon-street, E.C. Sir B. W. Richardson will take the chair and the speakers will be Colonel Coulson, Mr. E. Maitland, Mr. Herbert Burrows, Mr. Bernard Shaw, Mr. Josiah Oldfield, Mr. A. C. Field, and Mr. Dorrington Boyle.

WEDNESDAY.—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.). 8 P.M. Mr. W. C. Bosanquet: On the Anatomy of Nectotherus Ovis.—Dr. A. Bruce: A New Microtome for Cutting.—Miss Ethel Sargent: Some Details of the First Nuclear Division in the Pollen-Mother-Cells of Liliun Martagon, &c.

FRIDAY.—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-sq.).—8 P.M. Professor Lane Noller: Soil as a Factor in the Production of Disease.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 1 P.M., Mr. W. Lang: Lacrymal Affections.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. E. Law: Examination of the Throat and Nose.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Hypochondriasis.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Beevor.

LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 P.M., Mr. A. S. Morton: Retinal Affections.—Hospital for Skin Diseases, Blackfriars, 1 P.M., Dr. Payne: The Diseases called Lichen.

THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Dr. W. S. Colman: Stammering and other Speech Defects.—National Hospital for the Paralyzed, Bloomsbury, 2 P.M., Dr. Ormerod: Paraplegia.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. Reginald Harrison: Cases in the Wards.

FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 5 P.M., Prof. Crookshank: Examination of Air, Soil, and Water.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Percy Smith: Melancholia.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

UNDER no circumstances do the Proprietors authorise the insertion of loose advertisement circulars and handbills in THE LANCET. Any such announcements are inserted by the newsagents, whom the Proprietors cannot control. At the same time, the Manager will be glad if readers will send him copies of any circulars, with the name and address of the agent through whom they obtain THE LANCET, and the Manager will then endeavour to mitigate the nuisance.

NEWSPAPER THERAPEUTICS AND PERSONAL ADVERTISEMENT.

THE following is one among many answers to medical questions in the Echo of May 4th. The conduct of advising patients through the medium of a newspaper is at best not a very high proceeding, but when the writer practically divulges his personality and his address, as in the following advertisement (if, indeed, he be a medical man), he violates all the principles of professional method and modesty. The mere fact that the name is withheld does not affect the question. That may possibly be soon ascertained.

"(27,051) CATARRH.—Simply pass down the nose at night carbolated vaseline, and gargle with: acid salicylic, $\frac{1}{2}$ drm., acid boric, 2 drms.; mix; a saltspoon to a wineglass of warm water twice daily. She (*sic*) how you are in ten days."—Lennox (14, Connaught-mansions, Coldharbour-lane, S.W.)."

Lennox.—From the facts before us this case appears to be an extremely difficult one to advise upon; but we should think our correspondent has his remedy by proceeding against the authority for his fees, and procuring skilled medical evidence in his support.

THE CASE OF MR. C. B. TOWNSHEND.

The following additional subscriptions have been received and are hereby gratefully acknowledged:—

Dr. D. P. S. Cahill (Berwick-on-Tweed) ...	£1	1	0
Dr. B. Addy (Pendleton) ...	1	1	0

Further subscriptions will be thankfully acknowledged by the Rev. H. Townshend, 41, King Henry's-road, South Hampstead, N.W.

A CASE FOR DIAGNOSIS.

To the Editors of THE LANCET.

SIR,—A lady who was confined of her first child in a normal manner was suddenly seized with a rigor at about 11 A.M. on the ninth day. The patient was seen half an hour later and complained of feeling cold. The pulse was rapid, the surface of the body cold, the temperature in the mouth registered 102° F., and the breathing was hurried; vomiting occurred, first of the contents of the stomach, and later of bile. The shaking and shivering continued for an hour from the commencement, and then profuse perspiration set in; the cheeks and edges of the lips and mucous surfaces became livid, the inner surface of the lips was blanched, and the patient suffered from great dyspnoea and anxiety, with restlessness. She complained that sounds seemed at a distance and of ringing in her ears; also that vision was obscured, and that she saw things as through a yellow fog. About three hours from the commencement of the attack rather profuse menorrhagia set in, which lasted about three hours; vomiting continued; the heart's action was rapid, the first sound all but obliterated; and the pulse irregular and too rapid to be counted. The temperature was 96° F. All these alarming symptoms continued till about midnight, when improvement very gradually set in. The patient herself, although only semi-conscious, several times complained that she was dying, and when better said that she felt that she must give up the struggle for breath during the worst part of the attack. Recovery, after once setting in, continued without interruption. The treatment included stimulants by mouth and per rectum. Inhalations of oxygen also afforded great relief.

I am, Sirs, yours truly,

M.D. EDIN.

May 6th, 1895.

THE BOARD OF AGRICULTURE AND ANTHRAX.

The Times of May 5th states: "Some extraordinary statements as to the ravages of anthrax and the attitude of the Board of Agriculture in relation thereto were made at a meeting of the Leicestershire County Council yesterday. The disease broke out on the farm of a Mr. Warren at Arnesby, and not only the cattle but human beings and all kinds of animals were attacked. The farmer and sixteen men were all ill at one time, one man dying at the Leicester Infirmary. A woman in passing the plague-stricken spot was stung by a fly and died from anthrax. Cats, dogs, and birds in the neighbourhood also died. Sir Archdale Palmer stated that, in view of the seriousness and importance of the matter, the County Council had written asking the Board of Agriculture to send down an inspector to make an inquiry and report, but the Board had replied that they had not a professional officer to send down. A resolution was passed expressing regret that the Board of Agriculture had not seen fit to comply with the request of the Council."

Mr. A. E. Molloyes.—We never prescribe. Our correspondent should consult his own medical attendant.

Drayton.—It is not satisfactory to act as an anesthetist to a dentist who is not registered.

"MINERAL WATERS AS A BASIS OF MEDICAL ADVERTISING."

To the Editors of THE LANCET.

SIR,—I am one of the medical practitioners referred to in your correspondence columns whose names are used in connexion with certain mineral water advertisements appearing in the Croydon papers. Kindly allow me to say that my letter was intended merely as a polite acknowledgment of a case of the Association's mineral waters sent to me, and I had no idea that it would be used as an advertisement. I have written to the secretary, asking a discontinuance of the use of my name.

I am, Sirs, yours truly,

HENRY LOVE.

Mitcham, Surrey, May 6th, 1895.

* We have great pleasure in inserting the above letter. Our correspondent's experience shows the danger of writing letters to the proprietors of articles of commerce.—ED. L.

MEDICAL ADVERTISING.

Patient.—The first advertisement is not in good taste. The second is surprising in a Fellow of the Royal College of Surgeons of Ireland—a college which prides itself on its sense of dignity. The other advertisements sent us of testimonials of carriage from medical men are of a different order, and may be left to the taste of individual medical men.

Dubulator.—1. A university degree is certainly a desirable qualification and has some advantage over a mere licence.—2. We are not aware of any exceptional value of Irish licences as compared with corresponding qualifications in Great Britain.—3. There is no solid foundation for saying that Scotch degrees are not on a level with Irish ones, or even with Irish licences, though it is intelligible that "such an opinion may occasionally be heard in Ireland."—4. The degree of Aberdeen is a poor estimation.—5. The Dublin licences do not give a legal right to the title of "Dr."

Perpetrator.—A strictly proper form of plate and card for one with the quality named should indicate the name of the practitioner followed by the initial letters of the qualification.

FREE HOMES FOR EPILEPTICS.

To the Editors of THE LANCET.

SIR,—I observe in THE LANCET of the 27th ult. that, in answer to the inquiry of "R. W. (Newcastle-on-Tyne)," you remark that the National Society for the Employment of Epileptics is not at present able to receive non-paying patients at the Chalfont colony. Will you permit me to say that this is no longer the case, a special fund having been raised by means of which the committee are enabled to admit patients at either a reduced rate or entirely free in those cases where, after full consideration of all the circumstances, it appears to them right so to do. Unfortunately the accommodation at the colony is so limited, compared with the number of the applicants, that many candidates, whether able to pay or not, must necessarily be disappointed owing to want of room, and we most earnestly appeal to the generosity of the public to enable us to increase our buildings and provide accommodation less inadequate to the demand.

I am, Sirs, your obedient servant,

G. PENN GASKELL.

Secretary, National Society for the Employment of Epileptics, 12, Buckingham-street, W.C., May 7th, 1895.

Patient.—The question is a personal one between the druggist and his customer. We do not see any reason why a charge should not be made for a copy of a prescription, since the druggist had the trouble of recording the original, and is put to the further inconvenience of supplying a copy. But in any case a patient would do better to consult his medical adviser and not trust to "old prescriptions."

Subscriber.—We should say Yes, undoubtedly, but if the salary exceeds the amount which requires a return our correspondent must give the name of the assistant as an employee.

Mr. L. A. Wille.—See THE LANCET of April 27th, 1895, p. 1095, answer to "R. W."

ERRATUM.—In the notice of the case of Surgeon-Major Gardner in THE LANCET of last week ("The Services," page 1143, 1st col.) the date of his joining the service was accidentally printed as "1894." It should have been 1874.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—Leicester Post, Sussex Daily News, Western Daily Mercury, North Cheshire Herald, Bristol Times, Newcastle Chronicle, Birmingham Mail, Walsall Advertiser, Kidderminster Shuttle, Liverpool Mercury, Sheffield Independent, Carlisle Express, Macclesfield Chronicle, Oldham Standard, Kingston Express, Yorkshire Herald, Builder, Pioneer Mail, Scotsman, Courier de la Presse, Architect, Times of India, Elgin Courier, Sunday Times, Beverley Guardian, Ulverston Advertiser, Manchester City News, Brighton Gazette, The Charity Record, Rhyt Journal, Sheerness Guardian, Weekly Free Press and Aberdeen Herald, Reading Mercury, Sanitary Record, Hertfordshire Mercury, Yorkshire Post, City Press, Leeds Mercury, Bristol Mercury, Isle of Wight County Press, Liverpool Daily Post, Surrey Advertiser, Citizen, Mining Journal, Local Government Chronicle, Blackpool Herald, Galignani Messenger, Local Government Journal, Woodbridge Reporter, Penrith Observer, Sevenoaks Chronicle, Hastings Chronicle, West Sussex Gazette, Perthshire Advertiser, Falkirk Herald, Evening Telegraph (Dunder), Public Health, Newcastle Daily Leader, The Rock, Bedford Advertiser, British Weekly, Empire, Halifax Guardian, Clapham Observer, Pearson's Weekly, Clitheroe Times, Gloucester Standard, South Bucks Standard, &c., &c.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded. Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

A Clinical Lecture

ON A

CASE OF DISPLACED CARTILAGE.

Delivered at the London Hospital on Jan. 25th, 1895,

By C. MANSELL MOULLIN, M.D. OXON.,

F.R.C.S. ENG.,

SURGEON TO THE LONDON HOSPITAL.

GENTLEMEN,—The patient whom I bring before you is a young woman twenty-one years of age whose knee-joint you saw me open ten days ago for the purpose of removing the anterior half of the internal semilunar cartilage. The wound is healed, and although there is a little swelling around it and alight tenderness when it is pressed upon, the movement of the joint is perfect. In a few days it will be as strong and secure as the other one. Three years ago the patient met with an accident, slipping off the kerbstone and falling with her knee twisted under her. Whether the internal cartilage was torn at the time, or whether it was merely strained and then weakened by subsequent inflammation, it is not possible to say now, although the latter is the more probable. At any rate, ever since she has been liable, at intervals that were steadily growing shorter, to that peculiar form of injury known as internal derangement of the knee-joint. The knee, so she told us, was to all appearance as strong and secure as it ever had been. It could be flexed and extended through the normal range. She could walk on it and rest her weight upon it without discomfort. But if the foot was rotated outwards ever so little when the joint was partly flexed something slipped from its position, shot forwards so that it projected under the skin by the inner side of the patella, and locked the joint. Sitting upon a high chair with the foot off the ground the patient could swing the limb backwards and forwards as easily as she could the sound one; but when her weight rested upon it the joint was almost fixed in a position of partial flexion. This happened to her on several occasions, once whilst she was in hospital a few days before the operation, from sitting with her legs crossed, and each time it was followed by an attack of synovitis. There was no difficulty in reducing the displaced structure, although this does occasionally happen. Firm pressure over the projection while the knee-joint was alternately flexed and extended made the cartilage slip back into position at once; but as the displacement kept happening more and more frequently, and as each time it happened it caused severe pain and was followed by a smart attack of synovitis, the patient not unnaturally wished something to be done. This peculiar accident has been well known for many years. It was first described by Hey, who gave it the title by which it is known at present—viz., internal derangement of the knee-joint. Then Knott of Dublin published a further account of it from his own personal experience, and since then Allingham and others have continued to work at it and have thrown a good deal of fresh light upon it. It is caused either by the tearing or, as in the present instance, by the loosening of one of the semilunar cartilages from its attachment, so that it becomes displaced and is caught between the bones. The internal one, because its attachments are more rigid and less yielding, suffers more frequently than the external, and the anterior end more often than the posterior; but the posterior end may be torn, or the whole circumference may be separated and the cartilage curled up into the intercondyloid notch, or the cartilage may be split in two. The symptoms vary in character and severity, according to the nature of the injury. They are most marked when the displaced structure is caught and held between the bones. When it shoots forward, so that it lies quite out of the way or curls up in the notch, the pain and loss of power are not so great. Whatever the form, however, that the injury takes, it is always followed by an attack of synovitis, and this in course of time, if frequently repeated, becomes chronic.

The treatment of internal derangement of the knee is very simple in principle. The dislocation must be reduced as soon as possible, the limb kept at rest until the injury is repaired, only passive motion allowed, and cold and pressure

applied to check the effusion. Then—and this is the point to which I wish to direct your attention—steps must be taken to prevent recurrence. If the cartilage has only been slightly torn or strained it may in time recover and be as strong as it was before. But if the injury passes these very narrow limits, or if the accident happens a second time, breaking down the adhesions formed in the process of repair, such a result is not to be expected. The accident will occur again and again until either the cartilage is in some way made secure or the loosened part removed. For reasons that I will shortly give you I am myself strongly in favour of the latter course, the one that was adopted in the present instance. If the cartilage is to be retained it must be kept in position either by means of some mechanical appliance or by suturing it to the head of the tibia. Now the former of these is almost impossible unless the patient consents to give up all the pleasures of active life. The simplest contrivance is formed of a metal spring which passes horizontally across the limb behind the knee, and terminates at either end in a firm horseshoe-shaped pad. These pads rest upon the soft tissues in front of the knee and fit closely against the margin of the patella, one on each side. The idea is that the cartilage can be prevented from shooting forwards by the pressure in front. But this is only of use in a limited number of cases, for forward displacement is by no means the only kind that is met with; and even in these cases the degree of pressure that can be applied is entirely insufficient. Another appliance is formed of two lateral metal bars, hinged opposite the joint, and fastened by means of leather straps above and below the patella. This aims at keeping the disc in place by limiting the movement of the joint itself, especially in the direction of complete extension and rotation. But I need not tell you that all these appliances are cumbersome, very difficult of accurate adjustment, and only to be thought of in the case of patients who are well-to-do and are willing to lead a life of ease and quiet. For the young and active life-long restraint such as this implies is intolerable. If the cartilage is to be retained and fixation tried there can be no doubt that the plan of securing it by sutures to the head of the tibia as practised by Annandale is much to be preferred. I cannot, however, from my own experience entirely recommend this. Fixation by suture is seldom a permanent success except in those rare instances in which the circumference of the cartilage is detached from the tibia without the ends being torn. Where a previously sound cartilage has given way, or where one of the ends has been wrenched from off the bone, I am very sceptical as to whether it is possible to make it secure by means like this, and at the same time allow it to have its normal range of movement. Sutures and adhesions cannot make it stronger than it was before it was hurt unless they fix it so that it is completely rigid; and if it gave way before it will give way all the more easily a second time if exposed to a similar strain. I have tried suturing on two occasions, and in both patients the accident recurred. For this reason I am convinced that in all cases in which the cartilage is torn away from the bone, or in which although it may not be torn it is so stretched that it gets in the way of the bones and is caught between them, the knee-joint should be opened freely and the whole of the loosened part of the disc excised. The operation is one that at the present day, if proper precautions are taken and the patient is in a good state of health, can be performed with perfect safety. This is the fifth occasion on which I have done it for this purpose, and in none has the temperature risen to 100° F. It has the merit of being thorough; displacement cannot occur again. The risk is not greater than it is in fixing the cartilage by means of sutures. I myself am of opinion that it is less, as there is less manipulation of the joint, and the knee after the cartilage has been removed, and the wound is sound, is as strong and as free in its range of action as it was before the cartilage was displaced. This last statement, I know, has been disputed. The operation has been objected to, and is objected to, on the ground that it weakens the knee-joint by depriving it of a structure that is especially adapted to reduce the concussion caused by the sudden impact of the feet against the ground in jumping down from a height. Now I do not wish in any way to weaken your respect for authority. There are many statements in physiology as well as in other things incapable of proof, which you are expected to receive and accept on faith. But a little scepticism is often judicious, and if you quietly examine this objection I think you will agree with me that the respect which is due to tradition is almost the only foundation that it has. I do not believe that these cartilages are of any sensible use in

checking concussion even when they are sound and intact, and I am perfectly sure they are not if they are torn or displaced; in this state they are simply a source of danger. That they do serve some useful purpose is certain, or they would have disappeared. They are, as Bland Sutton has shown, the rudimentary representatives of the tendons of certain muscles found in some of the other vertebrata. In us the muscles have disappeared in the course of evolution; they were no longer of use and nature slowly but surely fails to develop useless structures. The tendons remain, and the fact of their remaining, however modified they may be in structure and appearance, is sufficient to prove that there is some work for them to do. But there is no evidence that this work is to act as cushions or buffers between the bones that form the knee-joint.

Consider for a moment the arrangement of these fibro-cartilaginous discs and I think you will agree with me that they are singularly ill adapted to such a purpose. Buffers are placed between the points of impact, but these are not, and, what is more, cannot be. The condyles of the femur do not rest upon them; they project through the central opening and rest upon the upper surface of the tibia. It is true that when the condyles roll forward upon the head of the tibia they press upon the thin margin of the cartilages in front; but in doing so they leave a large space that is free behind them, so that the discs slip forward at once (especially the external one) and escape. And it is also true that, when in jumping down from a height the femur is driven down upon the tibia, there is a certain flattening of the convex articular surfaces. The size of the area of contact must be increased a little under these conditions, but it is not increased sufficiently to bring the cartilages within the grip of the bones. As you can see in any series of instantaneous photographs, the shock in jumping is prevented so far as the knee is concerned, not by flattening of the bony surfaces of the tibia and femur, but by flexion of the joint. Flattening can be produced in the dissecting-room, but it takes place to a very small extent in real life. In short, instead of being formed to act as buffers, the shape and the slippery surfaces of the cartilages seem specially devised to enable them to escape from between the bones with the least amount of difficulty. The function that is left to them, and accounts for their continued existence, is entirely different from this. Their duty is to prevent the synovial capsule of the joint and the delicate peri-articular tissue from being driven in between the bones by the atmospheric pressure during rapid movements of the joint. You can easily imagine that with such an irregular mass as the lower end of the femur rolling backwards and forwards upon the upper end of the tibia, and with only a limited amount of synovial fluid in the joint, the intra-articular tension on different parts of the capsule must vary immensely and with the greatest rapidity in different movements. At one instant the front of the capsule is tense, the next it is relaxed and flaccid, and then, unless there is something to prevent it, there is imminent danger of its being sucked in and caught. This is the function of the discs to prevent, and they can prevent it so long as they are sound. When they are torn and displaced they are useless and worse than useless; they are positively harmful and are better removed. The tough cicatricial tissue that is left, tightening the capsule and drawing it outwards towards the skin, will take their place and prevent any trouble from this cause after they are gone.

REMARKS ON THE SURGERY OF THE RECTUM.¹

By BERNARD PITTS, F.R.C.S. ENG.,

SURGEON TO, AND LECTURER ON SURGERY AT, ST. THOMAS'S HOSPITAL;
SURGEON TO THE HOSPITAL FOR CHILDREN, GREAT ORMOND-STREET; CONSULTING SURGEON TO ST. JOHN'S HOSPITAL, TWICKENHAM.

THE surgery of the rectum, especially as regards treatment, has undergone many changes during the last few years, and my object is to touch very briefly upon points which appear specially to invite discussion. Since the adoption of scrupulous cleanliness in all details of operative surgery rectal surgery has been stripped of its dangers. The great

majority of operations are free from risk to the patient and from anxiety to the surgeon. The natural tendency has therefore been to aim at shortening the period of convalescence, and at the same time to make the cure as radical as possible. Unfortunately students during their hospital career cannot have many opportunities either for the examination of rectal complaints or for the close observation of operative manipulations, since the part does not allow of numerous examinations. Consequently medical men are apt to begin practice with the idea that there is something about rectal surgery which is mysterious and requiring special study. The same amount of care and attention and experience is requisite as for the surgery of any other part of the body; the same laws hold good; the diagnosis is, perhaps, if anything, easier to make than it is in affections of most other regions of the body; and the results after treatment are more certainly successful. The three most common conditions are fissure, fistula, and hæmorrhoids. Instead of the partial operation formerly practised, the aim now is the complete removal of disease, and, so far as can be done with safety, the immediate healing of the wound—in other words, to deal with disease of the rectum in much the same manner as with a similar affection in most other parts of the body. Complete dilatation of the sphincter is quite sufficient to cure many cases of fissure of the anus, but when the disease is chronic and the ulcer has an indurated base its complete excision is more satisfactory than the linear incision formerly recommended. Suture the small wound left after excision, so as to obtain immediate union, is not often successful, and personally I have given it up, for the raw surface is so shallow and narrow that the union obtained is pretty certain to break down when the bowels are allowed to act. In simple cases of fistula a complete resection of all cicatricial and sinus tissue shortens the period of convalescence very greatly, and I have never seen any harm arise when the parts are kept clean and packed with iodoform gauze. When the external opening is at some distance from the anus, and after excision a large deep wound is left, deep sutures to bring the sides of the chasm into direct approximation may repay the trouble taken, and a cure be brought about in a quarter of the time otherwise required. The wound must of course be carefully watched and the sutures removed if the part becomes contaminated. With ordinary precautions there is no increased risk in such an attempt at direct union—in fact, to put the matter shortly, “there is everything to gain, and nothing to lose.” Sutures are not advisable when the incision extends far up the bowel. In complicated cases of fistula, when the sinus extends round the bowel, or many secondary sinuses extend into the surrounding structures, a complete removal of all involved tissue should not be attempted. After freely laying the sinuses open it is best to be content with a free scraping of the lining membrane and the local application of some strong disinfectant, such as chloride of zinc, forty grains to the ounce. When a fistula is of tuberculous origin and it is thought desirable to interfere, it is of special importance that the removal of all affected tissue should be completely carried out; unless this is done the wound cannot be expected to heal, and the patient's condition will in all probability be rendered worse. It is not my intention to enter into a discussion on the question of operation in chronic phthisis, but it is my belief that such interference often turns out badly because half-measures have been adopted and the whole of the infected tissue has not been removed.

The three chief operative methods at present in use for the cure of internal hæmorrhoids are the clamp and cautery, ligature, and excision. I have not mentioned the pressure clamp, for I believe it is now universally given up as unreliable. The clamp and cautery treatment still has some advocates, but with the improvement in the preparation of silk ligatures the cautery is now not often employed. Personally I have not used it for quite ten years. By means of the ligature many forms of hæmorrhoids can be safely and satisfactorily treated; but the profession is indebted to Whitehead of Manchester for introducing the more complete surgical procedure of excision of what he describes as the “pile-bearing area.” This method is not necessary in the majority of cases. When hæmorrhoids are polypoid in character, and have healthy mucous membrane intervening, they can be quickly and efficiently removed by the ligature. In some cases, however, the whole circumference of the mucous membrane just within the white line is involved, and the condition is associated before or after stretching of the sphincter with prolapse of

¹ A paper read before the Harveian Society of London on May 2nd, 1895.

the unaffected mucous membrane above. A thoroughly radical treatment cannot then be carried out by means of the ligature, and Whitehead's method gives the most admirable results. It has always appeared to me strange that excision has not been more generally adopted in this class of case by surgeons. Some, indeed, after a limited trial have written against excision as an unnecessarily severe operation, involving the expenditure of time and the loss of blood, and likely to lead to stricture if the union at the line of suture fails and the bowel retracts. This is all very reasonable against the indiscriminate adoption of the method, but it does not in the least apply when suitable cases are chosen. I have adopted Whitehead's method now in about thirty cases, and am quite convinced that when there is a complete ring of hemorrhoidal tissue attended with prolapse to deal with it is the most satisfactory operation to perform. Failure to get a good result depends either upon the selection of an unsuitable case or upon a careless and imperfectly performed operation. The separation with scissors must be carried sufficiently high to allow the out edge of mucous membrane to be sutured to the skin with absolutely no tension. There is no occasion to hurry over the operation, and a skilled assistant is most desirable. Personally I do not trust to the sutures to arrest hemorrhage, but prefer to ligature bleeding points with very fine silk. The wound must be thoroughly disinfected and made dry before the sutures are tightened up. By a little extra expenditure of time a comparatively bloodless operation may be performed, and the risks of after-hæmorrhage are certainly less than by any method of ligature *en masse*. The sutures may be left to find their own way out and should not be removed unless any particular one is causing irritation. In only one case have I failed to get immediate union, and the cause of failure was the too free removal of redundant skin. In several instances my patients have been medical men, and they have been surprised at the small amount of after-discomfort, the painless evacuation of the bowels on the third and fourth day, and convalescence on the tenth day, together with the rapid regain of proper control over the motions. If immediate union of healthy mucous membrane to skin can be assured it is obvious that the patient has less chance of stricture than if a considerable portion of mucous membrane be destroyed by cautery or sacrificed by wholesale ligation. Since the internal and external sphincters are left intact, control over the contents of the rectum is no more endangered than by any other method of treatment, and as the whole of the pile-bearing area is removed the chances of relapse must be practically eliminated. Owing to the unavoidable interference with the nerve-supply at the anal margin a partial anaesthesia is often present for a little time, and if the patient has diarrhoea he may not be fully conscious of the presence of a little moisture about the anus, and this is the only objection which, so far as my experience goes, has any practical reality. I do not propose to touch on all the affections of the rectum, and shall now pass on to the treatment of stricture.

Congenital stenosis of the anus or rectum when complete demands immediate attention and can often be remedied by perineal exploration and after persistent dilatation. I will confine my remarks to the following two conditions—viz., (1) when the rectum ends by an opening into the floor of the prostatic or membranous urethra, and (2) when the rectum opens into the vagina. In the first condition an inguinal colotomy may save the child for a time, but death is likely soon to ensue from cystitis and surgical kidneys. In three cases under my care I have successfully relieved the distended bowel in this way, death occurring in from two to eight weeks from marasmus and cystitis, and at the necropsy in each case multiple abscesses were present in the kidneys. The abscesses were numerous, but quite small, none of them being larger than a pea. The only way to avoid this complication would seem to be by dividing the sigmoid flexure and so preventing any fecal matter from gaining access to the bladder. Hitherto I have refrained from this radical measure, hoping to be able at a later stage, by passing a guide from the colotomy opening, to establish by dissection a perineal opening. When a colotomy has to be performed because a perineal exploration has failed, and there is no evidence of a communication with the urinary passages, such later attempt to establish the perineal route might be successful, but it is only inviting disaster to strive for continuity of the bowel when meconium is being discharged from the penis. When the rectum opens into the vagina it is not uncommon to leave the abnormality alone and to wait for a few years unless

actual obstruction of the bowels ensues. Great harm may thus result from imperfect evacuation, the rectum and colon are likely to become enormously dilated, and permanent damage to their propulsive power may result. Such a condition is well illustrated by the following case.

CASE 1.—A girl aged eight years was admitted to the Hospital for Sick Children, Great Ormond-street, under my charge on Dec. 15th, 1894, in a much emaciated condition and with a greatly distended abdomen. The temperature was 104° F., the pulse 160, and the respiration 25. The tongue was dry and brown, and there were scordes on the lips and teeth. Examination showed absence of the anus and that the rectum ended by a small opening in the lower part of the vagina. A large fecal accumulation could be felt in the abdomen, especially in the left iliac region. The acute symptoms of obstruction had been present for ten days. Under an anæsthetic the opening in the vagina was dilated, and the finger was thus introduced into an immense rectal cavity occupying the whole of the pelvis and filled with feces. It was only after much time and trouble, and the use of twelve pints of warm water, that we succeeded in overcoming this fecal accumulation and getting the whole of the large bowel washed out. The child's condition was so critical, and she was suffering so markedly from ptomaine poisoning, that it was thought best to persist until we had completely relieved the obstruction. The result was satisfactory, all the febrile symptoms disappeared, and the child began to improve in general condition. This treatment under an anæsthetic, however, had to be again and again repeated, in spite of laxatives and enemata administered by the nurse. On Jan. 17th, 1895, an incision was made in the perineum, and the rectum brought down and fastened there. At the present time nearly all feces are passed by the newly formed anus; it will, however, be a long time before the dilatation of the bowel is overcome, and I much fear it will be a trouble through life. It now remains to close by a plastic operation the communication between the rectum and vagina. The proper treatment in an infant where the rectum opens into the vagina is to establish at as early an age as possible a patent opening in the perineum, and not to attempt any plastic operation on the vaginal opening until the parts are sufficiently developed to warrant a chance of success.

Besides congenital stenosis there may be a non-malignant stricture of the rectum from a variety of causes, such as syphilitic ulceration, dysenteric or tuberculous ulceration, ulcerative colitis, traumatism, and inflammation in the tissues around the rectum.

CASES 2 and 3.—At present there are under my care at St. Thomas's Hospital two well-marked cases of syphilitic stricture which illustrate exceedingly well the alternative methods of treatment. The first is that of a young woman aged twenty-five who had syphilis about two years ago. For several months past she had had difficulty and much pain in passing her motions. On examination the anus was seen to be surrounded by large thickened folds of skin ulcerated on the surface in places. The labia also were greatly thickened and indurated. On introducing the finger into the rectum a tight stricture could be felt extending from the anus for a distance of two inches and three-quarters and terminating abruptly in a cicatricial ring which with difficulty admitted the tip of the forefinger. Under an anæsthetic an incision was made completely through the stricture backwards towards the sacrum, and a plug of iodoform gauze was introduced. Such a stricture as this is almost certain to recur in spite of all care and treatment; the cicatricial tissue is so dense that it is not likely to be influenced by specific treatment. I propose to keep her under the influence of medicine for several months, and try how far dilatation can be maintained. In all probability it will be best later to excise the stricture and bring down healthy bowel to the anus. The second case differs considerably in character, and the anus and external parts are quite sound; the long tubular stricture of the rectum is probably dependent on a gummatous infiltration of the bowel. The patient, a woman aged thirty-three, was admitted on April 27th, 1895, with a greatly distended abdomen caused by obstruction of the bowels. There was no direct history of syphilis, but there were typical circular scars on the legs due to ulcers after a confinement eight years ago. During the last few months she had noticed that her motions had been small and pipe-like, and occasionally blood was passed on straining. No spurious diarrhoea was observed until fourteen days before admission, when she

began to pass blood and alime, but no formed faeces. At the same time her abdomen began to swell. The abdomen at the time of her admission was very distended and tense, and tympanitic on percussion, except in the left and right flanks. She was at once placed under an anæsthetic, and a rectal examination showed that about two inches from the anus the mucous membrane was cicatricial in character, and a tubular stricture extended as far as the index-finger could reach, the tip of the finger being gripped very tightly by the upper ring-like limit of the stricture. By means of the finger and graduated bougies the stricture was slowly dilated, and a rectal tube was then easily passed into the sigmoid flexure, and copious injections of soap-and-water and oil were administered. A little fecal matter and some flatus came away, and the patient was sent back to bed. On the same evening she had a severe rigor, the temperature rising to 105° F. and in three hours coming down to normal—a rigor very similar to the rigors which sometimes occur after passing an instrument along the urethra. In the following morning a large evacuation of the bowels took place, the condition having since been satisfactory, and there has been no further febrile disturbance. The case was one not suitable for treatment by proctotomy, and the choice was between dilatation—with, if necessary, limited incision—and colotomy. The stricture will be difficult to keep dilated, and as the length of the stricture and the general state of the patient's health contra-indicate excision of the rectum it is possible that colotomy may ultimately become necessary.

Removal of a simple stricture of the rectum is comparatively easy when the stricture is low down, but may be difficult or impossible when the inflammatory condition has extended beyond the wall of the bowel to the perirectal tissue. In one such case I was compelled to desist, so dense were the adhesions around the bowel.

CASE 4.—Stricture of the rectum after dysentery or ulcerative colitis may extend along its whole length and far up into the colon. A few months ago I was consulted by a man who three years before had had left inguinal colotomy performed for an intractable ulceration of the rectum, with constant discharge of pus and blood. The colotomy was carried out as a temporary measure and with the idea of giving the rectum rest. The ulcerative condition continued for one year and a half after the operation, and the patient, after waiting for more than a year longer, was anxious to have the natural passage restored. He was in good general health, but I was surprised to hear that since the operation no faeces had passed by the rectum. On making an examination under an anæsthetic this was explained, for the lumen of the rectum was almost entirely obliterated and the mucous membrane replaced by granulation tissue, which was exceedingly vascular. On introducing the finger into the colotomy opening the same condition was found to extend, but to a less degree, for about three inches higher than the opening. Such a condition was, of course, hopeless so far as the restoration of the natural passage was concerned.

As regards treatment malignant disease of the rectum may be divided into the following classes: (1) cases suitable for partial or complete excision of the rectum; (2) cases best treated by colotomy; (3) cases best left alone, or in which a lumen is provided by scraping out the central part of the growth; and (4) cases in which colotomy may be necessary for recurrence after excision. A growth situated low down in the rectum, recognised at an early period and before the disease has extended to the outer muscular coat of the bowel, is specially suitable for removal, particularly if the growth is on the lateral or posterior aspect of the bowel and is not attached to the prostate or bladder, and more especially when occurring in the female. I have said nothing yet as to the upward extension of the growth, for I regard this as of comparatively minor importance, since experience has proved that the peritoneum may be opened and the bowel drawn down with very little increase of danger to the patient. The healing of the wound when the upper part of the rectum or the end of the sigmoid flexure can be attached to the anus without tension is rapid, and the after-progress of the case much more satisfactory than when a considerable raw surface is left between the external orifice and the bowel. However easily the finger might reach above the growth, excision should not be attempted if there is evidence of fixation of the bowel to surrounding structures. Just above the prostate gland the rectum is normally somewhat fixed to the bladder, but with care is easily separated. I have no experience of Kraske's operation, and for simple excision of the bowel have never found any necessity to

remove either the coccyx or part of the sacrum. If the growth has not implicated the perirectal structures there is no difficulty as regards the separation of the rectum, and in all cases where the disease has extended beyond the bowel I do not believe that the removal is justifiable, for recurrence must be certain to take place at an early period.

CASE 5.—The following case shows how easily and with what a satisfactory result a growth high up in the rectum may be removed in the female. A woman aged thirty-three was admitted to St. Thomas's Hospital under my care on Feb. 17th, 1893. Her father's mother had died from cancer. Since August, 1892, she had noticed blood in her motions. For several weeks before admission blood had been constant with the motions, but she had not suffered much pain beyond the discomfort of straining after the bowels had acted. On rectal examination an ulcer could be felt on the anterior wall, at a distance of three inches from the anus, and about on a level with the cervix uteri. The ulcer was excavated, being about the size of half-a-crown, but with a raised hard margin, extending laterally for some distance round the bowel and as high as the finger could reach. The growth was freely movable with the rest of the bowel. An operation was performed on the 24th. An incision was made backwards through the sphincters to the coccyx, and stout silk ligatures were passed through on either side to act as retractors. The bowel was then divided all round just above the position of the internal sphincter and dissected up till the peritoneum was reached. After opening the peritoneum and dividing the meso-rectum the sigmoid flexure was brought down and the separated rectum was removed about one inch and a quarter above the growth. The bowel was brought down quite easily and sutured accurately to the anal portion of the rectum, which had been preserved. The posterior incision was packed with iodoform gauze. Recovery was uninterrupted, and she left the hospital on April 12th. I saw her quite recently, when she was in good health and able to follow her occupation. She had obtained complete control over her motions, for, although the whole of the rectum from just above the external sphincter to its junction with the sigmoid had been removed, yet the preservation of the lower end of the bowel, with the sphincter intact, had entirely deprived the operation of any of the usual after-inconveniences. The growth was examined by Mr. Shattock, and was a typical specimen of columnar carcinoma. The present condition of the seat of operation is most satisfactory, and after an interval of two years there is no sign of anything like recurrence.

CASE 6.—Sometimes complete prolapse of a growth may allow of its removal under exceptionally favourable circumstances. In January, 1892, I saw a man, with Mr. Bailey of Blackheath, who for some months had been losing blood occasionally from the rectum. He was a thin, sallow man fifty years of age, and he stated that on several occasions whilst straining at stool a large mass had appeared outside the anus and then receded. Under an anæsthetic, after free division backwards of the sphincters, we were able to feel a soft growth high up in the bowel, but were quite unable to bring it down into view, or indeed to do more than just touch its lower margin. It was decided to wait for its next appearance and then to secure it from recession by passing a clove-itch formed from a skein of thick wool round it. About a week later I received a telegram from Mr. Bailey saying that he had the growth successfully "at anchor." On my arrival I found a prolapse of bowel with a papillomatous growth, the size of a small orange, just outside the anus. The growth was sessile, and its base occupied a portion of the wall of the bowel, covering the area of a five-shilling piece. As the growth seemed to be infiltrating the muscular wall it was resected, together with the part of the bowel from which it was growing. The peritoneal cavity was thus opened, and we could see several appendices epiploicæ, showing that we were dealing either with the sigmoid flexure or with the first part of the rectum. A large number of interrupted sutures of silk were employed to bring the edges of the opening in the bowel together. Several pairs of forceps were left on the ends of some of the sutures specially passed for the purpose of preventing immediate retraction. These forceps were removed on the fourth day, and the prolapsed bowel was allowed gradually to retire. The patient made a good recovery and has remained free from rectal trouble or prolapse since. [The specimen which was submitted to the society showed a vertical section of the papilloma and the excised part of the bowel wall.] The muscular wall of the gut, though

displaced by traction, is uninvaded by any extension of the growth, so that the papilloma may be regarded as innocent in character. The growth could not, however, have been satisfactorily dealt with without excising completely its base of attachment, and the base, if left, might have assumed later a malignant character.

The malignant growths of the rectum best treated by colotomy are those which are unsuitable for excision and which are so occluding the bowel as to occasion or directly threaten obstruction. In some cases, though no obstruction exists, colotomy is demanded by the hæmorrhage, pain, and suffering caused by ulceration, and by the irritation of faeces passing over the affected part. Occasionally complications, such as the formation of fistulae or the establishment of a communication with the bladder, will necessitate colotomy. When colotomy is required it is far the best to divide the bowel completely across and so ensure that nothing shall afterwards pass into the rectum. In some cases the disease runs its course until the very last stage without causing much suffering or great inconvenience, and colotomy is never required. It may be argued that the growth will proceed more slowly if the part be placed at rest and all irritation from passing faeces removed. The natural objection to an artificial anus is so great that it seems hardly fair to urge it on a patient unless some definite object is to be attained.

CASE 7.—A fine healthy-looking man aged fifty was quite recently under my care at St. Thomas's Hospital with very extensive malignant disease of the rectum, infiltrating all the surrounding parts and extending far beyond the reach of the finger. The lumen of the bowel was apparently almost obliterated, yet he suffered no pain and very little inconvenience. The bowels were easily acted on by small doses of *cascara sagrada*. I could only advise him to wait, and to return for treatment if any difficulty about the bowels arose, at the same time warning him not to delay until the demand for relief was urgent. At present the patient looks in robust health and is quite capable of following his occupation.

In a few cases where the occluding growth is soft and non-vascular, as occasionally happens in very old people, obstruction may be prevented by scraping the central part of the growth away. This procedure is, however, rarely advisable unless the patient has an insuperable objection to colotomy. Colotomy may be necessary for recurrence after excision of the rectum, as the following case will show.

CASE 8.—In April, 1893, I removed the rectum for extensive malignant disease in a young man aged twenty-six, and in January, 1895, inguinal colotomy became necessary owing to increasing difficulty with the evacuation of the bowels. The general health was, however, good, and the recurrence at the seat of operation was not assuming an active character.

CEREBELLAR HÆMORRHAGE IN A YOUNG WOMAN; GLYCOSURIA; DEATH THIRTEEN HOURS AFTERWARDS.

By THOMAS OLIVER, M.D. GLASG., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

LITTLE has been written on the subject of cerebellar hæmorrhage. The rarity of its occurrence to some extent accounts for this. When a large quantity of blood is effused into the cerebellum the symptoms are generally sudden and severe, and the accident is usually fatal. Hamilton, in his text-book on Pathology,¹ says that the individual seldom lives longer than six hours, "probably from the pressure exerted by the swollen hemisphere upon the fourth ventricle. It may occur in young people, particularly in young women, and is due to a simple fatty degeneration of the small arteries and their capillaries." According to Ross,² when hæmorrhage occurs in the lateral lobe of the cerebellum there may or may not be loss of consciousness. There are occipital headache and vomiting, and if hemiplegia is present it is crossed or direct and due to pressure upon the pons. In minor cases marked rigidity of the neck has been observed, with paralysis of the orbicular muscle of the eyelid on the same side as the lesion; the pupils have generally been contracted and occasionally insensitive to light. On the other hand, a large hæmorrhage into the middle lobe of the cerebellum may, by

pressing upon the pons and medulla, cause the sudden development of apoplectic symptoms that speedily terminate in death. In some cases, however, fairly large hæmorrhages have taken place in the cerebellum without giving rise to any symptoms recognisable during life. The case I am about to report is not wanting in several points of interest. The patient, a young woman nineteen years of age, had apparently been in good health when she was suddenly seized with her fatal illness, which lasted thirteen hours, during which consciousness was never quite regained. The presence of sugar in the urine, accompanied by coma, suggested the probability of the case being one of diabetes, and as after death a large cerebellar hæmorrhage was found our attention was naturally directed to the relationship of irritation of the floor of the fourth ventricle and glycosuria which Claude Bernard first demonstrated. We have no knowledge that in my case the glycosuria preceded the cerebellar hæmorrhage. The naked-eye examination of the cerebellum at the necropsy failed to detect evidence of previous disease of that organ—not that this absence is any proof that glycosuria had not previously existed. If the patient was perfectly healthy at the time she received her fatal stroke—and the history of the case rather leans that way—then the glycosuria was a consequence of the cerebellar hæmorrhage, a circumstance all the more interesting to us as supporting Claude Bernard's demonstration. Schiff attributed experimental glycosuria to paralysis of the vaso-motor centre. After Claude Bernard's operations on the fourth ventricle the liver was always found engorged with blood—exactly the condition found in my patient. Ziemssen³ regards cerebellar hæmorrhage as difficult to diagnose, for the attack may or may not be accompanied by symptoms. Remak maintains that the occurrence of cerebellar hæmorrhage is always attended by vomiting and irregularity of the pulse. Vomiting is such a general symptom of intracranial disease that we cannot assign to it special significance in the diagnosis of cerebellar hæmorrhage. It was absent in my case. The fact that the effects of cerebellar hæmorrhage may pass away giving rise to no well-defined symptoms, that patients may live for years afterwards, and that post mortem a hæmorrhagic cyst may be found in the cerebellum, clearly indicates the difficulties that surround the diagnosis.

The history of the case is briefly this. Dr. William Robertson, who kindly sent the patient to me, first saw her an hour and a half after her seizure. It was in the forenoon. The girl had gone upstairs to her room and was found lying on her bed in a state of unconsciousness. The pupils were contracted and equal. There was no paralysis. The pulse was 22 and the respirations 10 to the minute. There were no signs of vomiting anywhere in the room. The reflex of the eye was lost. It was stated that the patient had been in excellent health the day before the attack. She was admitted into the Newcastle Infirmary shortly after Dr. Robertson's visit. She was then comatose. No murmurs were detected over the cardiac area. There was no peculiar odour of the breath and no evidence of poison having been taken. In the urine, withdrawn by catheter, there was no albumen, but a very large quantity of sugar. The pupils were equal, contracted, and did not react to light; there was, however, slight corneal reflex. The pulse was 80, irregular and full; breathing was deep and sighing. She was given two minims of croton oil, and later, by means of a soap-and-water enema, the bowels were moved. Two hours afterwards she was transfused with saline solution, but she never regained the degree of consciousness which a diabetic does under these circumstances. She died five and a half hours after the transfusion.

At the necropsy, on the second day after death, the body was found to be plump and well nourished. Rigor mortis was well marked. There was slight pleuritic adhesion of the right lung; the lungs were healthy, although engorged and oedematous. The heart was healthy. The liver was enlarged, weighed forty-eight ounces, and was red, soft, and friable. The spleen was normal. The pancreas presented nothing abnormal. The kidneys were engorged, their capsule stripping off readily. The uterus was parous; the ovaries normal. The cerebrum presented nothing abnormal; its vessels and tissue were healthy. In the middle lobe of the cerebellum a large recent clot was found. The superior surface and the posterior border adjoining the inferior surface of the middle lobe were lacerated, exposing the clot of blood. The tissue of the cerebellum was soft. On laying open the

¹ Vol. ii., part 2, p. 602.

² Diseases of the Nervous System, vol. ii., p. 597.

³ Vol. xii., p. 154.

cerebellum the clot was found to extend right across the centre of the organ, approaching quite close to the surface on either side and splitting up the cerebellum into an upper and a lower layer. There was no evidence of new growth. A portion of the clot was lying outside the posterior surface of the cerebellum, having lacerated its substance. The membranes of the brain and cerebellum were healthy.

Newcastle-on-Tyne.

A SERIES OF CASES OF OPERATIONS UPON THE STOMACH.¹

BY HERBERT W. ALLINGHAM, F.R.C.S. ENG.,
SURGEON TO THE GREAT NORTHERN CENTRAL HOSPITAL; ASSISTANT
SURGEON TO ST. GEORGE'S HOSPITAL.

IN going through my case-books I find that I have on thirteen occasions operated upon the stomach. Although I regret there is nothing new to report, yet the experience I have gained from these operations tempts me to narrate them and to point out some of the lessons that I have learnt. I have performed gastrostomy seven times, gastro-enterostomy four times, Loreta's operation once, and pyloroplasty once. I will now briefly relate the cases as they came under my charge.

CASE 1. *Gastrostomy* (1).—A man fifty-two years of age had had for a year great difficulty in swallowing, and for the last month had been unable to pass into the stomach even liquids. He had lost much flesh, and appeared to be in the last stages of starvation. On examination an oesophageal bougie stopped on a level with the central part of the sternum. There had been constant vomiting of blood and mucus. On Aug. 14th, 1886, gastrostomy was performed. An incision three inches long was made parallel to and half an inch from the margin of the ribs. The abdominal cavity was opened; the stomach was found and was secured by many interrupted stitches passing through the muscular and serous coats, and was thus fixed to the skin wound. The patient was fed per rectum and progressed favourably till Aug. 21st; as he was weak and failing in general strength the stomach was opened, and food was given every four hours until the 23rd, when he died. A post-mortem examination showed that there were no signs of peritonitis; the stomach was firmly glued to the abdominal wall. The cause of death was asthenia.

CASE 2. *Loreta's operation*.—A patient fifty-four years of age was admitted into the Great Northern Central Hospital with pyloric obstruction. There was no tumour to be felt. The patient was much emaciated and constantly vomited soon after taking food. After a consultation with my colleague, Dr. Burnet, it was decided to explore the pylorus, and if the obstruction was not malignant to perform Loreta's operation. On May 13th, 1888, the abdomen was opened by a vertical incision in the median line just above the umbilicus. The pylorus was found to be freely movable but rather thickened, and appeared to be in no way affected by malignant disease. The liver, as far as it could be examined, was normal. The thickened condition of the pylorus showed a fibrous state. The stomach was opened on its anterior surface, the incision being large enough to admit three fingers. When the finger was inserted into the stomach the pyloric opening was found to be greatly contracted. Only with great difficulty could one finger be inserted, but by gradual dilation it was possible, after a time, to pass two fingers through the contracted portion. No ulceration was to be felt. The stomach wound was sewn up with Lembert's sutures. The patient was rather collapsed after the operation and died the next day. On post-mortem examination the body was found to be much emaciated; the stomach walls were well glued together, there was no leakage into the peritoneum, and there was no evidence of peritonitis. At the back of the liver there was a small cancerous nodule. The pylorus was freely dilated and showed on section a scirrhus condition. There was no ulceration of the mucous membrane.

CASE 3. *Gastrostomy* (2).—A man forty-eight years of age was admitted into the Great Northern Central Hospital. For four months he had had difficulty in swallowing, and had experienced pain in the epigastrium and the lower sternal regions. For two months he had been unable to eat solid

food, and liquids returned at once even when slowly taken. He had lost 2 st. in weight in three months, and while in the hospital a week lost 1 st. more, so that at the time of the operation he weighed only 7 st. On July 9th, 1890, gastrostomy was performed. A vertical incision was made in the left linea semilunaris, the abdominal cavity was opened, and the parietal peritoneum was stitched to the skin. The anterior part of the stomach was sought for near the cardiac end, and was placed in position by the method of "quilled suture" advocated by Mr. Greig Smith. The patient did well and was fed for the first week with nutrient enemata. The stomach was then opened by an incision large enough to admit a No. 8 catheter; through this the patient was fed and he rapidly gained in weight. After this he went to the cancer wards of the Middlesex Hospital, where he lived for eleven months. The authorities of that hospital kindly informed me that his death was caused by the cancerous growth extending into the lungs.

CASE 4. *Gastrostomy* (3).—A woman fifty years of age was admitted into the Great Northern Central Hospital. For six months she had had difficulty in swallowing solids and for two months had been restricted to fluid nourishment. She was wasting rapidly. On the right side of the neck a swelling was noticed. No bougie could be passed beyond the level of the upper border of the sternum, and in this situation there was a cancerous mass. On Dec. 30th, 1891, gastrostomy was performed. A vertical incision was made in the left linea semilunaris, the parietal peritoneum was stitched to the skin, and the stomach was kept up to the abdomen by Greig Smith's "quilled suture" method. The patient was fed by nutrient enemata. On Jan. 3rd, 1892, the stomach was opened by a small incision, and into this was passed a No. 8 catheter, by which food was given. On Jan. 6th all the stitches were removed; on the 17th, at the request of her friends, she left the hospital. She lived four months longer.

CASE 5. *Gastro-enterostomy* (1).—A woman forty-seven years of age was admitted into the Great Northern Central Hospital on Feb. 24th, 1892. From October, 1891, she had had occasional attacks of sickness and pain in the epigastric region, which usually occurred in the evening. A burning sensation in the epigastrium preceded the sickness, the vomited matter consisting of the meals taken during the day. A few months before admission a swelling was noticed in the epigastric region. The patient had lost a good deal of flesh. The abdomen was not distended. About the epigastric region could be felt a hard nodular growth, about the size of a Tangerine orange, which was quite movable, but was painful on examination. The bowels were obstinately confined. On March 2nd the abdomen was opened above the umbilicus in the middle line by an incision four inches long. The stomach was explored and a hard growth was found involving the pyloric end. The anterior wall of the stomach was then drawn into the wound, and an incision one inch and a half long was made in the stomach; a coil of jejunum was similarly drawn out and incised to the same extent. Two Senn's bone-plates were inserted, one into the stomach and the other into the jejunum; the bone-plates were then apposed, thus bringing together the aperture in the stomach and in the bowel. The plates were next tied together, and the stomach and bowel were united by twelve superficial Lembert's sutures. The abdomen was sponged out, and the abdominal wound was united by silk-worm-gut sutures. After the operation the patient vomited some blood-stained fluid, and continued to vomit intermittently for twenty-four hours. For four days she was fed per rectum, and after that food was given by the mouth. On March 14th a purge was given, which acted well. The patient progressed favourably, with occasional vomiting after meals, especially when the food was of a very bulky nature. On May 30th she left the hospital, having gained in weight, and went to the north of England. Four months later she died from some lung trouble, probably of a malignant nature; her friends declined to allow a post-mortem examination to be made.

CASE 6. *Gastrostomy* (4).—In June, 1892, a man sixty-seven years of age came to the Great Northern Central Hospital. For twelve months he had had difficulty in swallowing; for the last five or six months his diet had been confined to fluids, and even these sometimes returned. The obstruction was on a level with the upper part of the sternum. For two months he had lost flesh rapidly, his normal weight of 11 st. being reduced to 8 st. at the time of admission. No bougie could be inserted more than twelve inches from

¹ A paper read before the Medical Society of London on May 13th, 1896.

the teeth. On June 22nd a vertical incision two inches and a half long was made along the left linea semilunaris, the abdomen was opened, and the parietal peritoneum was stitched to the skin. The anterior wall of the stomach was pulled out into the wound, and was then drawn through the hole in a Senn's bone-plate, which was placed transversely to the wound in the abdominal wall. A piece of the stomach was then drawn through the hole in the bone-plate and was held in position by two harelip pins passed through the muscular and serous coats. This operation (Bowman Jessett's) took ten minutes to perform. The patient was fed by enemata till June 27th, when the stomach was opened by a tenotomy knife in the interval between the harelip pins. A No. 8 catheter was introduced into the aperture and the patient was fed through it. On June 30th the pins and bone-plate were removed. On July 19th the patient left the hospital, being much improved in health and having gained considerably in weight. He was heard of eight months after the operation, but no information was received as to his further length of life.

CASE 7. *Gastrostomy* (5).—A man fifty-one years of age began to experience trouble in swallowing at Christmas, 1891, and this difficulty so increased that five weeks before his admission to the Great Northern Central Hospital in August, 1892, he was unable to swallow any food. He was greatly emaciated and a bougie would not go beyond ten inches from the teeth. On Aug. 31st a vertical incision two inches and a half long was made in the left linea semilunaris, the abdomen was opened, and the parietal peritoneum was stitched to the skin. The transverse colon was discovered, and thence, by tracing up the great omentum, the stomach was easily found. Part of the anterior wall near the cardiac end was then drawn through the hole in a Senn's bone-plate (Bowman Jessett's operation). The patient was fed by enemata till Sept. 5th, when the stomach was opened in the interval between the harelip pins by a tenotomy knife; through the opening in the stomach thus made food was given every four hours. On Sept. 7th the pins were removed. The patient, who was greatly improved, left the hospital on Sept. 20th. There was no information given as to the time he lived after the operation.

CASE 8. *Œsophagostomy followed by gastrostomy* (C).—A woman fifty-three years of age was admitted into the Great Northern Central Hospital at the end of September, 1892. For many months she had had much difficulty in swallowing solid food, and of late had had great trouble in swallowing fluids. At times she vomited blood and mucus; she had lost flesh and was much emaciated. After examination with bougie and finger, she was believed to have a malignant stricture on a level with the cricoid cartilage. This was thought to be a fit condition for the performance of Œsophagostomy. Therefore, on Sept. 29th an incision was made down upon the left side of the neck; the Œsophagus was found, brought to the surface, stitched to the skin wound, and then opened. The next day, as the patient was feeble, a catheter was passed into the Œsophageal opening, and through this catheter food was administered. But to my amazement, as fast as the milk was poured into the Œsophagus it ran out again; moreover, when the catheter was passed down towards the cardiac end, by no persuasion could it be made to find its way into the stomach. This being the case, gastrostomy was performed by Bowman Jessett's method. Then the stitches connecting the Œsophagus with the skin were cut loose, so that the Œsophagus fell back into its normal position. On Oct. 1st the stomach was opened and feeding was at once commenced. The patient made an uninterrupted recovery, the Œsophageal opening completely closed, food was given daily by the opening in the stomach, and the patient gained rapidly in weight, leaving the hospital at the end of October; about two months later, as she failed to pass the catheter into the stomach some friends assisted her to do so, but unfortunately they passed it instead into the peritoneal cavity, into which fluid was poured; needless to say, within twenty-four hours she died from acute peritonitis.

CASE 9. *Pyloroplasty*.—In June, 1894, a man thirty-one years of age entered the Great Northern Central Hospital. Seven years before, his illness began with an attack of what was supposed to be acute dyspepsia, and since then he had been treated for that ailment. Two years before admission he had attacks of acute pain in the pit of the stomach, which occurred at no particular time of the day, but very frequently. A year later he began to be sick, usually at

night, vomiting the meals eaten during the day, but never blood. Just before admission this vomiting took place nightly, on one occasion amounting to three quarts of partially digested food. The bowels were very constipated, acting only once a week and the motions being scanty. He had attended at another hospital, where he had had the stomach washed out frequently, and all kinds of drugs had been tried for his relief. The patient was a spare man. The stomach was much dilated, but no tumour was to be felt in the abdomen, and the other organs were quite normal. On June 20th the abdomen was opened in the middle line by an incision extending from the ensiform cartilage to the umbilicus. The pylorus was sought for and found to be thickened and contracted. There were no signs of malignant disease; thereupon it was decided to perform pyloroplasty. A longitudinal incision was made running transversely to the stricture. The pylorus, when so opened, was found to be much contracted and fibrous. The centres of the edges of the longitudinal cut were then pulled apart, so that the incision was converted into a transverse one. This incision was then sewn together by a deep suture, which united the mucous membrane on one side of the wound to that on the other side, and the muscular and serous coats were united by many of Lembert's sutures. The patient made an uninterrupted recovery. The stitches in the abdominal wound were removed on June 28th; for some days previously the patient had been fed by the mouth with milk and essence of meat, and from that date solid food was given. He continued to take by the mouth diet of various kinds without sickness or pain. He left the hospital on July 10th, having gained much in weight. He was seen again in February, 1895, when he was in perfect health and able to eat everything without experiencing sickness or discomfort. At that time he was shown before the Medical Society of London.

CASE 10. *Gastro-enterostomy* (2).—In July, 1894, a woman forty-four years of age was admitted into the Great Northern Central Hospital. For eighteen months she had complained of great pain in the stomach after meals, followed some hours later by severe vomiting. This had grown much worse of late. She had rapidly lost flesh, and for the last three months had noticed a swelling about the epigastric region, which had increased in size and was very painful when handled. The patient was much emaciated, and about the epigastric region could be felt a large, hard, irregular mass. All food taken was returned, and the vomited material was sometimes blood-stained. As it appeared from the symptoms to be a case of tumour of the pylorus, it was determined to perform gastro-enterostomy if it was possible. On July 12th the abdomen was opened in the middle line by an incision extending from the ensiform cartilage to the umbilicus. On exposing the stomach there was found what appeared to be a large, hard, sarcomatous mass which involved the pylorus and a considerable portion of the stomach. There were also secondary deposits in and about the great omentum. This condition caused me considerable doubt as to whether it was possible to perform gastro-enterostomy on account of the extent of the growth and the amount of stomach involved. However, after much consideration it was decided to be justifiable to attempt the operation, in the hope that it might afford some relief. An incision was made into the anterior surface of the stomach, and a piece of jejunum about twelve inches from the duodenum was brought to the surface and similarly incised. Mayo Robson's bobbin was inserted into the holes in the gut and stomach and fixed, and these apertures were brought together over the bobbin in the manner described by Mr. Mayo Robson. It should be noted that the jejunum was fixed up to the stomach, so that when the contents of the stomach passed along the jejunum they might proceed in the direction in which food usually goes along that gut. The abdomen was then closed in the customary manner. The patient made a rapid and uninterrupted recovery, and was soon fed by the mouth with all varieties of food. She left the hospital in about a month's time, and was shown by me before the Medical Society of London in February, 1895, together with Case 9. She was perfectly well, and had gained 3st. in weight. It was curious to note that the growth about the epigastrium was still present, but it had not increased in size, and perhaps had even diminished.

CASE 11. *Gastrostomy* (?).—A man forty-eight years of age was admitted into the Great Northern Central Hospital on Nov. 12th, 1894. For sixteen months he had had some difficulty in swallowing, which had rapidly increased of late.

He was scarcely able to take liquid food and had lost much flesh. No bougie could be passed beyond the middle level of the sternum. There was no history of syphilis. On Nov. 14th gastrostomy was performed by a vertical incision two inches and a half long; a small knuckle of stomach was fixed through Senn's bone-plate by Bowreman Jessett's method. On Nov. 20th the stomach was opened, a No. 8 catheter was tied in, and the patient was fed every four hours. In this case the opening in the stomach must have been made rather too large, for at times through the fistula there was a discharge of gastric juice (and some food) which greatly irritated the parts around the aperture. The patient left the hospital on Dec. 2nd, and was still alive in May, 1895.

CASE 12. *Gastro-enterostomy* (3).—On Nov. 28th, 1894, a woman twenty-six years of age was admitted into the Great Northern Central Hospital under the care of Dr. Beevor, my colleague. For two months she had complained of pain in the epigastrium with some distension and heaviness after meals. In November she began to vomit all food, but this relieved her great pain; the vomited material was sometimes blood-stained. On admission there was observed in the umbilical and right lumbar regions a distinct, rounded tumour, which was nodular and hard. There was no jaundice or ascites. On Dec. 10th the growth was rapidly increasing, and the patient was losing flesh and becoming worn out by the pain. Two days later (Dec. 12th) an incision was made in the middle line from the ensiform cartilage as far as the umbilicus. The tumour was found to be irregular in shape and involving the pylorus and neighbouring parts; moreover, the right lobe of the liver was adherent to the tumour. Remembering the success of a similar case (Case 10) I determined to perform gastro-enterostomy. An incision was made into the anterior surface of the stomach and a similar one into the jejunum; the openings were brought into contact over a Mayo Robson's bobbin and were fixed together in the manner advocated by that surgeon. For a few days there was considerable vomiting, evidently of fluid coming from the small intestine. This was remedied by causing the patient to sit up in bed instead of lying down. On Dec. 20th all the stitches in the abdominal wall were removed, and the abdominal wound was soundly healed. On this date the patient asked for food, and her general condition greatly improved. She continued for some time to make progress, put on flesh, and was quite relieved of abdominal pain. However, on Jan. 12th, 1895, she was suddenly seized with great pain in the abdomen, vomiting began, and she died from peritonitis on the 13th, thirty-three days after the operation. A post-mortem examination showed that the gastro-enterostomy wound was soundly healed and that the communication between the stomach and jejunum was quite perfect, admitting the middle finger. The cause of death was ulceration of the growth on the anterior wall of the stomach spreading into the general peritoneal cavity and thus setting up purulent peritonitis.²

CASE 13. *Gastro-enterostomy* (4).—On Jan. 28th, 1895, a man forty-five years of age was admitted into the Great Northern Central Hospital. Twelve months previously he had begun to have attacks of vomiting at intervals of fourteen days; these did not occur after meals, but generally took place at night. The quantity vomited varied, sometimes amounting to two or three quarts, and consisted of all the food which had been taken during the day. In November, 1894, his condition became much worse, and he rapidly lost flesh. Five years before he had weighed 15 st.; on admission his weight was only 9 st. 4 lb. The abdomen was very full, the muscles were rigid, and some peristalsis could be plainly seen through the abdominal walls. The stomach appeared to be enormously dilated, and extended as far down as the right Poupart's ligament. Considerable splashing could be elicited. On Jan. 30th the abdomen was opened above the umbilicus; the stomach was found to be enormously dilated, and about the pyloric end, which was brought up from the neighbourhood of the right Poupart's ligament, a hard carcinomatous mass was seen and felt. The anterior surface of the stomach was opened by a small incision, and the same was done to the jejunum. Into these openings a Murphy's button was inserted and the operation was completed as advised and carried out by Professor Murphy. Two anchor stitches were employed to fix the jejunum to the stomach. The patient was not at all collapsed and passed a good night. The temperature was normal and there was no vomiting

On Feb. 1st there was slight vomiting and the patient complained of thirst. There was no distension of the abdomen or tenderness. On the 3rd there was still slight vomiting. As the stomach continued to be greatly dilated it was washed out, and three pints of very offensive fluid were removed. The patient was much collapsed after this "washing out," and died early the next morning. A post-mortem examination showed that there was enormous dilatation of the stomach; the Murphy's button was in no way blocked, the gastro-enterostomy wound was quite sealed, there was no leaking into the general peritoneal cavity, and there was no trace of peritonitis and no distension of the intestines.

Remarks.—It will be seen that I lost one of the gastrostomy cases, one of the gastro-enterostomy cases, and the one in which Loreta's operation was performed. I may at once remark that if operations upon the stomach are to be of any use—that is to say, brought to a successful issue—the operation must be done fairly early—i.e., before all chance of recuperative power is gone. It may be observed that my first case of gastrostomy died nine days after the operation simply from asthenia. The gastro-enterostomy case died from what I can only describe as the result of an enormously over-distended and probably septic stomach—in other words, a stomach that had become so dilated that it had passed the point at which it was possible for it to recover its contractile power. Now, with regard to the best incision in the abdominal wall for exploring the stomach, if the operation is for gastrostomy, I conclude, after trying various incisions, that the vertical one about the left linea semilunaris is the best. On the other hand, when the pylorus is to be dealt with, or when a gastro-enterostomy is required, I am of opinion that a vertical incision in the middle line above the umbilicus is the most desirable. It is well known that in many of these cases, especially when the disease is an œsophageal stricture, the stomach is contracted and drawn up well under the ribs. There is sometimes difficulty in finding this organ, and again, even when it is found, there is occasionally trouble in making sure that it is the stomach. This may be overcome as follows. First of all, upon opening the abdomen a search should be made for the transverse colon (which is immediately recognised by the longitudinal bands); and then the great omentum (the gastro-colic portion) should be traced up to the lower edge of the stomach. By these means the stomach can always be quickly found, and, moreover, there will not be the slightest doubt that it is the stomach. The next point to consider is the choice of the operation to use in gastrostomy. I have tried several methods, and have no hesitation in saying that the method advocated by Mr. Bowreman Jessett is by far the best. This is done by drawing a piece of the stomach through the hole in a Senn's bone-plate, which is placed on the skin in a transverse direction to the abdominal wound. The stomach is held in position through the bone-plate by two harelip pins. This prominent part marks the stomach, which can be opened by a tenotomy knife passed into it between the harelip pins. By this method there is not the slightest difficulty in finding the stomach, and in opening it when feeding is commenced that way. Again, very few stitches are required; in fact, none are needed to fix the stomach to the abdominal parietes. The operation is rapidly done, a quarter of an hour being ample time. Another point is of great importance. When one is opening the stomach the orifice should be only large enough to admit a No. 8 catheter. If the orifice is made any larger there is great likelihood of the food regurgitating through the fistula and causing much irritation of the skin around the opening. Too large an opening was made in Case 11, and this, I think, was the cause of the regurgitation, which gave the patient great annoyance. While discussing the points I have noticed in gastrostomy cases, I must not forget to note the curious fact that often—i.e., in five of my cases—as soon as the stomach was opened, and the patient was fed in that way, the stricture of the œsophagus was evidently relieved of spasm, and at times the patients were able to take fluids fairly comfortably by the mouth. This happy state, however, was of course intermittent. There are only a few remarks to make about the operation of gastro-enterostomy. I do not like Senn's plates. I do not think they keep the lips of the wound in the stomach or intestines sufficiently apart, and, therefore, later, the opening between these viscera is often not large enough. I feel certain that the opening was not large enough in Case 5, for it will be remembered that after the operation

² The specimen was shown.

the patient often vomited bulky foods. Now, by the use of Mayo Robson's bobbin, or Murphy's button, the lips of the incisions in the stomach and intestines are kept well apart, certainly for some days, and thus there is little or no fear of the openings between these organs being too small. The loss of Case 13 (gastro-enterostomy) was in no way due to any fault of Murphy's button. In fact, the union between the stomach and the intestine around the button was quite good. Pyloroplasty, which I employed in Case 9, I regard as the best operation for the relief of non-malignant stricture of the pylorus. By it a healthy piece of stomach is let into the anterior surface of the pylorus; moreover, the stricture is divided and relieved, and no doubt in time becomes absorbed. I have doubt as to the lasting benefits of Loreta's operation, and I can readily understand that in dilating a rigid stricture it might easily be torn through, with a consequent leaking into the peritoneal cavity. Again, dilating a fibrous stricture does not always cure it, as may be instanced in many cases of urethral stricture. In the case in which I performed this operation, death, I think, resulted from shock and asthenia, the patient being very ill when the operation was attempted.

Grosvenor-street, W.

THE ROLE OF ALCOHOL IN THE TREATMENT OF HEART DISEASE.¹

By CHARLES W. CHAPMAN, M.D. DURH.,
M.R.C.P. LOND.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART,
SOUTH-SQUARE.

AN observer of many cases of heart disease cannot fail to be struck by the well-nigh universal recourse to alcoholic stimulants by these patients as an indispensable part of treatment. After making a fair allowance for cases in which the taking of alcohol in immoderate quantities is attributed to medical prescription, but which are really independent of it, there remains a not insignificant proportion of patients who habitually consume a large quantity of spirit, apparently under professional advice. Whatever the true reason may be the fact remains that many sufferers from various forms of heart disease take alcohol under the conviction, not only that it is a good thing for them, but that it is essential to their very existence. That alcohol is valuable in some cases and on particular occasions there can, I think, be no question, but I am thoroughly convinced that it is a grievous error to order this stimulant in all cases. If it be true, as I believe it to be, that alcohol should never be prescribed except after full consideration, with a definite object in view, in measured doses and, as a rule, in stated doses, emphatically is it so in the treatment of heart disease. A glance at the more common forms of cardiac disease will be a help in the discussion of this question. The degenerations affecting the myocardium, whether coming on in the course of an acute illness or caused by the diminution of blood-supply consequent upon atheromatous changes in the coronary arteries, lead to dilatation of the chambers of the heart. This is evidenced by a tendency in the patient to faintness or actual syncope. The physical signs are increased, cardiac dulness (unless pulmonary emphysema is also present), indefiniteness of the apex beat, and muffling or even loss of the first sound. Such a patient, liable as he is to cardiac failure, should have a stimulant of some kind always at hand. It is against the injudicious use of alcohol that I am anxious to protest. Alcohol, when not really needed, does mischief by unduly exciting the already weakened heart, and indirectly by interfering with the general nutrition through the disgust for food which generally accompanies gastric catarrh of alcoholic origin. It must be remembered that an already congested mucous membrane is easily irritated. Patients of the above class are not uncommon in the out-patient room. They generally complain of having a weak heart. They have an alcoholic appearance, the true cause of which is confirmed by their own statement that "they take whisky every now and then to keep themselves up." On further inquiry it will be found that these patients have

frequently an intolerable sinking sensation at the epigastrium. This sensation is often erroneously called fainting and is considered to be an indication for the use of alcohol; whereas the symptom frequently owes its existence to excess in spirit drinking. The histories of these patients show excess of some form of alcoholic liquor, extending, it may be, over many years—in fact, ever since they have, rightly or wrongly, got it into their heads that they have "a weak heart." The beer-drinker is generally bloated in appearance, with a liver enlarged out of proportion to his cardiac difficulty, and he has much subcutaneous fat. The spirit drinker, though sometimes fat, may be thin, and his liver may be even contracted. The symptoms in both classes when there is degeneration of the myocardium are practically the same, though the treatment may not be identical. The beer-drinker is perhaps more liable to pulmonary emphysema, which masks the percussion evidence of cardiac enlargement. It would appear that excessive beer-drinking is directly responsible for some cases of heart disease. In a quotation from the *Blätter für Klinische Hydrotherapie*² in THE LANCET the following occurs: "It is said that disease of the heart is very prevalent in Munich, where the consumption of beer amounts to 565 litres per head annually; and in the same place the duration of life in the brewing trade is shorter than that of the general population." The tremulous, flabby, or over-red tongue of the drinker is unfortunately too common to need description. When, in addition to the ordinary signs of intemperance, we have dyspnoea which the condition of the lungs will not fully explain, degenerative changes in the heart and bloodvessels should be suspected and renal changes sought for. The physician who thoughtlessly prescribes alcohol in these cases or fails to define the dose and clearly state under what circumstances it may be taken incurs great responsibility. If food is better taken with a stimulant and light wine is unsuitable, then half an ounce of brandy or whisky in three ounces of water may be taken at meal times. The frequent doses of alcohol should be stopped and a mixture containing ether and ammonia be used as an occasional stimulant, while medicinal treatment should be directed towards the relief of the congested portal system. By these means the appetite returns and assimilation is improved, judiciously selected cardiac tonics completing the cure as far as possible. Sir Thomas Watson in his classical lectures³ remarks: "For that fatty ruin much may be done even by drugs, and more by counsel and warning, for his safety; when syncope is threatened diffusible stimuli may be freely used. Above all, you must inculcate temperate habits and a life of constant quiet. These cautions are, indeed, more or less applicable to all cardiac disorders, but they are especially requisite whenever there is reason to suspect that the texture of the heart is infirm and incapable of bearing the stretching of a hurried or an impeded stream of blood."

CASE 1.—A man aged sixty years, engaged in shipping, consulted me on Jan. 26th, 1894. He complained of weakness of his heart, palpitation, and giddiness on ascending stairs. The giddiness sometimes came on in the early morning. He had been generally strong and had had no serious illness. The symptoms commenced eleven months previously. Examination of the lungs gave no evidence of disease. Cardiac dulness was generally increased; the apex could not be clearly defined. In the recumbent position the action of the heart was visible as gentle undulations; the sounds were feeble; there was no bruit. The radial arteries were thickened and tortuous. There was no albumen in the urine; the liver was a little enlarged, and the tongue was furred. The patient, who had lived freely for years, had increased his allowance lately on account of his symptoms. The amount of spirit was reduced to two ounces daily in divided doses with lunch and dinner. Strychnine and muratic acid were given. On March 1st the giddiness had ceased and he felt better. The heart's action was stronger. Subsequent notes showed progressive improvement.

Another class of patients who complain of weakness of the heart belong to what may be called the neurotic variety. These complain of præcordial pain, or of pain under the left breast, and palpitation and irregular action of the heart. So convinced are these patients of the serious nature of their complaint, and of the consequent necessity for alcohol, that they look quite disappointed when informed that they have no heart disease, and are astonished when told that the very

¹ Read (without the cases) before the West London Medico-Chirurgical Society, Jan. 4th, 1895.

² THE LANCET, Aug. 29th, 1891.

³ Principles and Practice of Physic, vol. ii., p. 273.

thing which they supposed had kept their heart going was responsible for many of its difficulties. These patients are for the most part females, prone to feel their pulse every now and then. They are anæmic, have been working too much, or—what is more exhausting to the nervous system—have been pleasuring in excess. The former are generally large tea-drinkers; the latter, in addition to over-much tea, have perhaps been beguiled into taking so-called medicated wines, and from these insidious and dangerous compounds have gone on to brandy, or even actual narcotics. Such patients, when in the absence of organic disease they complain of palpitation and irregularity of the heart's action, require neither stimulants nor cardiac tonics. Abstinence from the cause or causes of the disturbed innervation of the heart, with the kind of rest requisite in each case and proper diet and medical treatment, will most tend to recovery of health. In chlorosis, with cardiac dilatation especially of the right side, where, as Dr. Foxwell has shown,⁴ the apex beat is abnormally high in consequence of the dilatation, and, moreover, where there are signs of regurgitation through the mitral valve, the failing and weak heart does not simply require to be fillipled with stimulant, but rather needs a minimum of work until its tone is sufficiently restored to enable it to take on full duty. Rest, even in bed, fresh air and sunlight if possible, together with light nutritious food, are the first essentials. Then, if the tongue is clean and the bowels are open, ferruginous, with possibly cardiac, tonics will in most cases lead to a satisfactory result. The heart shares in the general improvement, and, the valves now being competent, regurgitation ceases. In men palpitation and irregularity of the heart are in certain cases caused by business anxieties, indigestion from hurried and irregular meals, and excess of alcohol and of tobacco. To give these patients stimulants is only to add fuel to the fire. In doubtful cases it would be wiser to withhold stimulants or give them very cautiously.

CASE 2.—A woman aged thirty-two years, who had had four children, consulted me for palpitation and giddiness under exertion or excitement. These symptoms were of four months' duration. There was no history of any severe illness. The patient went a great deal into society; latterly she had acquired the habit of taking brandy in the early morning as well as during the day to enable her to keep her engagements, and on her own responsibility had taken sulphonal at night to induce sleep. Of course, there was little or no appetite. There being no evidence of organic disease in the chest or elsewhere, I suggested that she should give up to a large extent her dinner parties and balls and devote herself to the more wholesome home duties, that she should take no spirits, but have beef-tea with cayenne pepper when the desire for stimulant came on, and substitute bromide of ammonium for the sulphonal. In three weeks the improvement was most marked, the cardiac symptoms had entirely disappeared, and she was much less nervous. As for brandy and sulphonal tabloids, she had "none of them."

CASE 3.—A girl aged sixteen years consulted me on June 14th, 1894. She complained of breathlessness on the slightest exertion, and of fainting attacks; her pallor was extreme; the legs were greatly swollen up to the knees. Menstruation had commenced three years previously; she had been regular and well until seven months before, when she was first noticed to be getting pale and weak. She had had no serious illness; the lungs were good, but the heart was enlarged, there being a soft systolic bruit at the mitral and pulmonary valves; the liver was not down; the urine contained a faint cloud of albumen, probably from admixture of vaginal discharge, and there were no casts. There was slight lateral spinal curvature. She had taken iron, but with no benefit. The mother was anxious to know whether stimulants were necessary. The treatment consisted of increased rest in bed, and it was suggested that she should lie on her back in the open air for two hours daily. Light nourishing diet was given, but no stimulants, with medicine to improve the colour of the blood. In six weeks she was of a healthy colour and in good health; the heart sounds were normal, and the menses had returned. Ferruginous tonics with rest succeeded when the former alone had failed.

Aortic stenosis.—A patient having an aortic systolic bruit, but free from regurgitation at either cardiac orifice, and,

moreover, if he has no syncopal or epileptic attacks, is not in a very sorry plight. His life may even be insurable, with some "loading" of the premium. The heart will probably have undergone salutary hypertrophy, and provided that extra strain be avoided his heart need not trouble him. Would it not be absurd to prescribe measures having the avoidance of undue strain for their object, and at the same time to allow the heart to be goaded on with stimulants? These remarks apply with double force if adequate compensation has not been established and there is reason to fear that the left ventricle is still yielding. Rest in a recumbent position, fresh air, and such tonics as strychnine and iron, with or without digitalis, constitute a line of treatment much more likely to lead to satisfactory results than stimulation.

Mitral stenosis.—In this condition, although there is from the beginning great strain on the left auricle, the right ventricle is soon stimulated to increased effort, and hypertrophy of both chambers results. When the right ventricle is doing its utmost to urge the blood through the pulmonary circuit (the tension even leading at times to hæmoptysis) on to the already distended left auricle, and finally to the narrowed mitral orifice, it would be worse than useless to further excite the heart. Yet one comes across patients having this lesion, whose vital functions are being carried on fairly well, taking alcohol simply because they have been told they have "weak hearts." Smallness and feebleness of the pulse may in some cardiac affections be indications for the use of some stimulant, but in the condition under consideration the left ventricle would not be found wanting if only it could get an adequate amount of blood to pump on.

Aortic regurgitation.—Patients having aortic incompetency are specially liable to fatal syncope. Regurgitation through the mitral valve, indicating as it often does dilatation of the left ventricle, enhances this liability considerably. Alcohol is certainly a valuable item in the treatment of these cases. Careful discrimination, however, as to when this remedy is called for and when it would be injurious is as necessary in patients of this class as in others of a less serious nature. I have seen cases benefited and others injured by stimulants, and I think it is a good rule to reserve their use for emergencies. My experience leads me to the conviction that, in the earlier stages at any rate, little or no alcohol is required. If, associated with the valve lesion, there exists an atheromatous state of the arteries undue excitement of the heart would tend to precipitate a fatal rupture of a weakened vessel.

CASE 4.—A married woman aged fifty-five years came under my care on Nov. 18th, 1892, complaining of dyspnoea on slight exertion, rheumatic pains in various parts of the body, and attacks of palpitation. She had had rheumatic fever (after scarlet fever) at fifteen years and again at thirty-six years of age. She had taken small doses of spirit frequently during the last ten years, had been gradually getting worse, and now the least exertion brought on breathlessness and pain. The patient was stout, with a dusky, yellowish complexion. The heart was considerably enlarged downwards and to the left, the action somewhat feeble and intermittent, and there was a double aortic bruit; the liver was enlarged, the urine free from albumen, and the pulse characteristic. The amount of whisky was materially reduced and measures taken to improve the circulation and to relieve the congested viscera. In a short time, with the exception of a very small quantity at meals, no stimulant was taken. Without pursuing in detail the progress of the case, suffice it to say that undoubted benefit followed the treatment, and that both her heart and general condition are much better now than they were two years ago.

Mitral regurgitation.—A patient with this form of heart disease pre-eminently requires his treatment to be varied according to the exact condition he is in at the time of consultation. Alcohol should no more form a necessary item in treatment than that valuable but much misused drug digitalis. Dr. Byrom Bramwell⁵ remarks on the treatment of progressive mitral regurgitation: "Excesses of all kinds, more especially over-indulgence in alcohol should be strictly forbidden." Later he states: "Alcohol is not necessary in this [early] stage of the disease. Persons who have been accustomed to the use of wine or other alcoholic stimulants may be allowed a small quantity of alcohol, but the quantity should be strictly moderate; a larger amount is not only hurtful in itself, but by producing a tolerance on the part of the system robs us in the later stages of the

⁴ THE LANCET, Nov. 14th, 1891.

⁵ Diseases of the Heart, p. 468.

disease of one of our most effective therapeutic means of arousing the falling heart to greater energy."

CASE 5.—A man aged fifty-eight years consulted me in March, 1892, for severe shingles affecting the distribution of the right supra-orbital nerve. On examination of the chest I discovered a loud mitral regurgitant bruit. The patient, observing I was examining his heart, remarked that he had had a murmur ever since an attack of rheumatic fever twenty-eight years ago, but as it had never troubled him in any way he had taken no notice of it. He was a very active business man and lived abstemiously. In this case there was doubtless perfect compensation, the loudness of the murmur being evidence of power in the heart muscle. He subsequently developed Bright's disease, with arterial rigidity, and in a year died from cerebral hæmorrhage. Had this patient taken immoderately of alcohol, or heightened his blood pressure with digitalis, it is very probable that he would have succumbed earlier.

CASE 6 *Mitral regurgitation with heart failure.*—A young woman aged twenty-two years was seen by me on Dec. 21st, 1893, in consultation with Mr. Dickinson of Southfields. Twelve years previously, when consulting Mr. Dickinson for some trifling ailment, a mitral systolic bruit was discovered. In the absence of cardiac symptoms, and of any history pointing to a cause for organic heart disease, the condition was presumed to be "functional." Early in 1893, on arriving home after a hurried walk, she had an alarming fainting attack, which initiated other symptoms of cardiac failure. I saw her eleven months afterwards. On examination the heart was found to be much enlarged downwards and to the left, both lungs were deficient in resonance, especially at their bases posteriorly, with coarse crepitation. The heart was so tumbling about that the mitral bruit which had previously been noted could not be made out. The liver was much enlarged and the urine high-coloured but free from albumen. The patient was propped up and was breathing with much difficulty. Treatment which had been successful up to a recent period seemed to fail, and recourse to more stimulant appeared to be necessary, especially as nourishment caused nausea and vomiting. Calomel in fractional doses was ordered, and measures for further treatment and nourishment agreed upon. It was arranged that the effect of abstinence from stimulants, except when absolutely necessary, should be tried. The patient remained in the same critical state for four days, after which time improvement slowly and steadily set in. Mr. Dickinson's last report, on Sept. 24th, 1894, states that "with the exception of her inability to go out of doors the patient is very well. As regards the stimulants, I found she did very well without them; hardly any were given after you saw her, as no emergencies arose."

CASE 7. *Dilated heart from strain after influenza.*—A man aged thirty-two years, of a nervous temperament, consulted me on Sept. 15th, 1894, complaining of pain in the cardiac region, with aching down the left arm and dyspnoea on exertion. He had influenza twice in 1892, and in February, 1893, he had a third attack. While the temperature was still high he fulfilled an engagement to play in an amateur theatrical performance. His strength did not return; accordingly, after two weeks he went on a visit to the Channel Islands. One day, while riding on the sands, the horse bolted for the distance of four miles. Although an experienced rider, the exertion and excitement were too much for him at that time. On dismounting he had pain in the chest and faintness, but during the following day, feeling much better, he went for a walk, when, on ascending a hill, the pain and oppression in the chest were so intense that he had to stop where he was until a carriage was sent for him. The medical man who saw him said he had strained his heart. On examination the heart's apex was found to be at the fifth space in the nipple line; the impulse was feeble and diffused. A soft systolic bruit was present at the apex and heard nearly as far as the left scapular angle; the other organs were healthy. Though not prone to the use of much stimulant, he had taken more than usual since the heart symptoms declared themselves; he always carried a small flask of brandy in his pocket. The first point in treatment was to assure the patient that he need not specially fear sudden death; further, that there was a fair prospect of his making a good recovery. In conjunction with other measures a "loafing" holiday was recommended with exercise short of fatigue, and abstinence from stimulants excepting a small quantity with his meals. Improvement

was gradual, and by Jan. 16th last (four months after the first consultation) it was noted that he could go upstairs without inconvenience, and that the bruit could scarcely be heard. Now it is not claimed that the reduction of the consumption of alcohol was the sole cause of the successful issue in this case, but it can scarcely be denied that it was an important item in the treatment.

As a rule in the history of cases of valvular and other serious forms of heart disease, symptoms of cardiac failure appear sooner or later. The action of the heart becomes weak and faltering, the contractions being frequent and ineffectual; dyspnoea is provoked by the least possible exertion, or is even a constant condition; the liver is enlarged, there is increasing œdema of the lower extremities, and probably albuminuria is present. In such a desperate case, hanging, as it were, between life and death, the most natural thing is to give stimulants freely, and sometimes this is all that can be done. If, however, the right side of the heart can be relieved by bleeding or by a calomel purge, and stimulants only given when actually necessary, stagnation in the circulation is diminished, and an improvement in the symptoms may perhaps follow. The calomel may be given in doses of two or three grains, or the same amount in frequently repeated fractional doses.

The late Dr. Mahomed, the value of whose observations on the circulation is generally acknowledged, makes the following remarks: "It is not infrequent to find over-full vessels associated with a weak and failing heart; the pulse is then often small and feeble; it is very easily compressed and is described as a small weak pulse, which is thought usually to require stimulants. The reverse, however, is the case; bleeding or purging will be well borne by such patients and the result will be most satisfactory." The question as to how far stimulation may be advisable in an individual case or not must be answered by the medical man in attendance. The existence of extreme cyanosis shows that the immediate difficulty is with the right side of the heart, and consequently this must at any rate be relieved. This having been accomplished, every effort must be made by appropriate treatment and diet to improve the muscular power of the heart. Alcoholic stimulants may be required, but it should be remembered that they are not always necessary and may even be harmful. It will be seen that though alcohol has its place in the treatment of some phases of heart disease, the necessity for it in all cases has been questioned and unbridled licence to the patient has been condemned. The lay mind is as convinced of the need for stimulants in all heart cases as of the call for whisky whenever a symptom can be in any way attributed to gout or rheumatism; in the latter case it is not over-difficult to successfully oppose the patient's belief, but where the heart is concerned it is at times well-nigh impossible to do so. Indeed, no small amount of courage may be required to enable the medical attendant to carry his point. No rules for the guidance of the practitioner can be laid down; each case has its own individuality. Moreover, the symptoms in heart disease vary often day by day, or even from hour to hour, so that it would be the height of folly to attempt to dogmatise on so important a question. Routine is a snare to be guarded against in treatment generally; in cases of heart disease its consequences may easily be fatal.

Weymouth-street, W.

ON SO-CALLED TROPHIC INTESTINAL AFFECTIONS IN THE INSANE.

BY F. W. EURICH, M.B., C.M. EDIN.,
PATHOLOGIST, COUNTY ASYLUM, WHITTINGHAM, PRESTON.

ANOTHER morbid process has been added to the already long list of "trophic lesions" in an interesting article by Dr. T. P. Cowen of Prestwich Asylum, published in THE LANCET of March 16th under the heading "Trophic Intestinal Affections in the Insane." The old conceptions of trophic action and its immoderate use in explaining obscure lesions, once so strongly combated by Cohnheim and others, seem again to be in the ascendant, although recent advances in the knowledge of the ground-plan upon which the nervous system is built up and of the physiology connected therewith tend somewhat to modify views regarding "trophic action" and caution us against its indiscriminate application. A vague term, it does not appear to be a physiological entity. Hence the use of it should be a guarded one; and only

after a most careful use of the method of exclusion, and after close microscopic examination of the nervous apparatus implicated in cases apparently similar in nature, should such lesions as may be under consideration be attributed to "trophic action." Do Dr. Cowen's "trophic intestinal affections" meet these requirements? Has the nervous system been microscopically examined, and has every other possibility been excluded? It may be assumed that the former has in all probability been omitted—the results would else have been briefly noted in his paper. The other point invites closer examination. All cases suspicious of tubercle, typhoid fever, Bright's disease, syphilis, or dysentery have, it is remarked, been excluded. Of these diseases four will not have offered many diagnostic difficulties, but the fifth is an exception. The clinical features described in the first part of the paper, and the illustrative cases reported in the second, raise the not unnatural question, How have some of these cases been differentiated from dysentery? And this interest is continued into the account of the pathological appearances. Of course, reference is not made to tropical amoebic dysentery, but to that form of "dysentery" or dysenteric diarrhoea which is more or less common in many asylums. As a case in point I would instance No. 8 in the accompanying table. Diarrhoea with tenesmus; blood, slime, shreds of tissue and sloughs in the stools; and moderate pyrexia and constitutional disturbance are common to dysentery and to Dr. Cowen's "intestinal lesions." The same classes of patients are affected by each; the pathological appearances seem to be identical. Wherein lies the distinction? That asylum dysentery should be a trophic lesion is out of the question; and it remains to be seen whether these other ulcerative processes can justify the appellation of "trophic," assuming them to be a pathological entity. The examination of this subject should be divided into three parts: (1) an inspection of Dr. Cowen's arguments; (2) a brief summary from the clinical and post-mortem records of the asylum for the past three years; and (3) various objections that remain to be stated.

Five arguments are brought forward to support the theory of trophic origin: (1) the rarity of such lesions in the sane, (2) the comparative frequency in the degenerate insane, (3) negative evidence as to causation, (4) their association with other trophic lesions, and (5) the association of such lesions with disease of the central nervous system. Passing these reasons in review, I will leave the first and second for a time and turn to the third. This needs but little consideration, for general negative evidence does not warrant the adoption of a theory unless supported by other and stronger facts with which it stands or falls. Two of these facts are contained in Arguments 4 and 5. It is a pity that Dr. Cowen has omitted to mention what other trophic changes were found (if any) in his illustrative cases. Only in one (transverse myelitis) has a small bed sore been deemed worthy of note. This omission greatly weakens his theory; but if there has in reality been nothing to omit his arguments of necessity fall to the ground. Till the association of these intestinal affections with trophic lesions elsewhere is demonstrated their association with disease of the central nervous system is valueless and can only be looked upon as a complication unless other reasons are forthcoming. Gangrene of the lung, vastly commoner in the degenerate insane than among the mentally sound, might with no less plausibility be classed among the trophic lesions. Lastly, the rarity of these intestinal lesions in the sane and their relative frequency in the degenerate insane claim our consideration. In this comparison lies a fallacy. The comparison is an unfair one, for the terms are unequal. The nervous system, in virtue of its wide and intimate relations with all parts of the human frame, cannot be extensively diseased without in some way lowering the vitality of other organs. A special trophic action need not be called to account for this; the heart is no less trophic to the lungs, or the blood to the central nervous system. It is simply the law of the inter-relation of parts. The insane patient, then, is, when attacked, in a degenerate condition; his whole vitality lies low—a necessary consequence of the disease with which his central nervous system is afflicted. If the intestinal affections are not trophic—and let it be assumed that this is so for the present—they must be due to agencies which find in these cachectic conditions, *sit venia verbis*, a favourable opportunity to display their full activity. Such a wretchedly low vitality or cachexia as we see in these poor lunatics is to be found in but a few bodily disorders of the mentally sound; of these the commonest besides malignant

disease are tubercle, syphilis, and Bright's disease, the very three that have been excluded from consideration. Insanity leading to frailty of constitution must be looked upon as a predisposing cause, must stand side by side with Bright's disease or syphilis, and with these only is comparison permissible. The following explanation, then, would appear to be as rational as the theory of trophic origin. The active agent comes from without—e.g., hygienic conditions, the nature of the ingesta, &c.; lowered vitality is the preliminary postulate, while the cause of such deficient vitality may vary—in one case it is Bright's disease, in another syphilis, and in a third some form of insanity.

Two hundred necropsies have on the average been performed every twelve months for the past three years at the County Asylum, Whittingham. Out of this number fifteen only remain for consideration after all cases suspicious of tubercle, syphilis, Bright's disease, typhoid fever, or dysentery have been excluded. It may not be unimportant to state here that *not one* of our dysenteric patients was a general paralytic. The clinical features of these fifteen cases require but a few words. The stools have shown great variety as regards their frequency, quantity, consistence, and colour. Slime was often found, but never sloughs or shreds of tissue, and in one case only were the dejecta streaked with blood. In five cases death was due to the intestinal affection. Seven patients were eaters of filth and otherwise depraved. Ulceration, never extensive, was found in the intestines, most frequently in the colon, of six patients, four of whom were eaters of filth &c. A feature of interest is the swelling of the mesenteric glands, in some cases without ulceration; this condition would be difficult to explain on the lines of a trophic theory. As for other trophic lesions, none were found save malformation of the nails in some half-dozen cases.

Table of Cases.

No.	Case.	Sex.	Age.	Condition of intestines.	Remarks.
1	Epileptic dementia.	M.	38	Catarrhal enteritis; ulceration; perforation.	Eater of filth: twigs, leaves, and bits of newspaper found in small intestine.
2	Acute melancholia.	F.	57	Two duodenal ulcers (healing).	Artificial feeding: death from septic pneumonia.
	General paralysis.	M.	33	Ill-defined congestion of small intestine.	Death from general paralysis and lobar pneumonia.
4	Acute mania of general paralysis.	F.	42	Catarrh of ileum; no ulceration.	Death due to exhaustion from mania.
5	General paralysis.	M.	43	Slight catarrh of ileum; swollen glands.	Diarrhoea (stools streaked with blood) three days before death; great feebleness and emaciation.
6	Epileptic dementia.	M.	40	Follicular ulceration of colon; septic absorption.	Filth-eater.
7	Primary dementia.	F.	41	Slight catarrh of lower end of ileum; no ulcers.	Filthy habits; death from pneumonia.
8	Chronic mania.	F.	38	Atrophy of muscular coats.	Death from pneumonia and gangrene.
9	Epileptic dementia.	M.	60	Catarrhal colitis.	Eater of filth &c.
10	General paralysis.	M.	53	Ileum congested; swollen mesenteric glands.	Death from lobar pneumonia.
11	Epileptic dementia.	F.	45	Patchy congestion of ileum; swollen mesenteric glands.	Diarrhoea for three months; death from pneumonia.
12	Epileptic dementia.	F.	41	Catarrh of ileum and colon; no ulceration.	Great rachitic deformity.
13	Primary dementia.	M.	37	Follicular ulceration of colon.	Filth-eater; gangrene of lung.
14	Idiocy.	M.	38	Catarrhal enteritis and colitis; follicular ulceration.	Filth-eater; occasional diarrhoea for years.
15	Secondary dementia.	M.	58	Follicular ulceration of descending colon.	Death from gangrene of lung.

It now remains to be seen whether there are other reasons why the trophic theory should be guardedly, if at all, advanced. One or two occur to me, and they are mainly anatomical. The ulcers are described as bearing resemblance in some instances to the round, gastric ulcer *par excellence* dystrophic. Now, the trophic origin of this ulcer is not by any means indisputable; but, granted it were, there has never yet been seen post mortem a gastric ulcer combined with similar processes in the lower alimentary tract. Not only has such an instance not been found in the pathological records of the asylum, but it is doubtful whether there exists a case in point from literature. Such cases must be very rare, and almost valueless because of their rarity. To return to the intestinal ulcers themselves, why should the solitary follicles be so frequently singled out by inflammatory and necrotic processes? Their affection does not appear to be a secondary one, and they are perhaps the last structures of the intestinal mucosa to be expected to succumb to dystrophic nerve influence. Only the assumption of some organismal or toxic agency seems to offer a fair explanation. The part of the gut affected is also peculiar. Trophic influence is no respecter of regions. If the stomach can become the seat of a dystrophic lesion there would appear to be no reason why the next sixteen or seventeen feet of intestine should escape as they do, especially if the medulla oblongata, in which so many centres are crowded into so small a space, be considered the seat of the central trophic mechanism. A possible explanation, however, might be that the gastric and intestinal secretions are more or less interfered with by the nervous disorder. Faulty digestion results, and the lower reaches of the gut come in contact with food, unprepared, and different from what they have been used to cope with. The functions of the liver are also perverted—small, flabby, atrophic livers have frequently been found in the degenerate insane—and the bile expends all its properties, especially its disinfectant power sooner than normal in its downward passage. All these factors tell upon the ileum and large intestine; abnormal excretion gives rise to disturbed function which in time ends in lowered vitality. There is no need to go on with the argument; it dovetails with what has gone before.

This then is the position: the theory of trophic origin cannot be accepted as a satisfactory explanation of all intestinal affections met with in the degenerate insane—and tubercle, syphilis, &c. have been excluded. Neither can it be said that trophic intestinal affections never occur; but they must be very rare, much rarer than Dr. Cowen believes them to be. Only the careful sifting of cases and minute examination of the nervous system hand in hand with experiment will assist in the differentiation of truly trophic lesions from other obscure ulcerative processes in the lower alimentary tract.

Whittingham, Preston.

A CASE OF MULTIPLE ADENOMATOUS POLYPI OF THE LARGE INTESTINE ASSOCIATED WITH CARCINOMA BOTH IN THE SIGMOID FLEXURE AND LOWER END OF THE RECTUM.¹

By CHARLES A. MORTON, F.R.C.S. ENG.,

Surgeon to the Bristol General Hospital; Demonstrator of Anatomy, University College, Bristol.

THE association of innocent and malignant growths is always interesting, because it raises the question of the possible transformation of the one into the other. It is thought by some that this may occur in cases of long standing, fibro-adenoma of the breast, or papillomatous growths on the tongue and elsewhere, while few would, I imagine, deny the liability of moles to become the seat of melanotic sarcoma. But great caution is necessary before we conclude that because innocent and malignant growths are found in contact one is necessarily a transformation from the other. We ought to trace microscopically the change from the innocent into the malignant form. For instance, fibro-adenoma of the breast is a very common disease, and so is scirrhus; and because we find a

scirrhus growing in contact with a fibro-adenoma we have no right to conclude that one is a transformation of the other unless we can microscopically trace the change in the fibro-adenoma, which might be reasonably considered an early stage of the cancerous growth. When we have a wart on the tongue or elsewhere, which has existed as such a long time, and then can be seen microscopically to invade the deeper structures at some parts as well as to take on clinical features of malignancy, the transformation becomes almost certain. The adenoid cancer in my case might start either in the polypi or in the mucous membrane between them; in either case it would destroy the polypi by ulceration, and that it has done so is almost certain, for the areas around the cancerous growths are covered with them. Proof that the cancer started in the polypi is impossible unless we can trace the gland tissue of the polypus actually growing downwards into the submucous tissue; but, at any rate, there seems little doubt that the tendency to the production of adenoid polypi is in this case associated with a predisposition to the development of malignant adenoma also. Disseminated polypi of the large intestine is a rare disease. Mr. Cripps² says he can only find three specimens of multiple polypi in a search through the London hospital museums, and that he had only seen two cases during life. Yet in several cases³ it has been associated with cancer, and in two instances⁴ with cancer both in the rectum and elsewhere in the large intestine. This seems to me to suggest a causal relationship. Adenoma of the breast is very common; carcinoma also is very common—and what is more likely than that they should be occasionally associated in the same breast without any causal relationship?—but multiple adenomata of the large intestine are rare, and their frequent association with cancer is highly suggestive of a transformation from the innocent to the malignant form of growth.

The patient whose case I am about to describe was a woman aged forty-five years, who was under the care of Mr. Dacre in the Hospital for Sick Children and Women last year, to whom I am indebted for kind permission to publish the report. The case came under my observation during the time I was pathologist to the hospital. The whole of the large intestine was studded with growths. There must have been several hundred. Some were minute sessile elevations of the mucous membrane the size of a pin's head, others were larger and distinctly pedunculated, and one or two had pedicles a quarter of an inch in length. These larger growths were soft, like velvet. To a certain extent they resembled mucous membrane, but were rather suggestive of a papillomatous nature. Both the minute sessile and the larger pedunculated growths were least numerous in the cæcum, and did not extend into the ilium. They became exceedingly numerous in the lower part of the colon, the sigmoid flexure, and the rectum. They seemed only attached to the mucous membrane, and the intestinal wall was not thickened. At the lower end of the sigmoid flexure some of the growths, though pedunculated, became much flattened, and attained the size of a shilling, or even of a florin, resembling a mushroom, except that instead of being attached to the intestinal wall by a round pedicle, the pedicle consisted of a linear attachment of the centre of the flattened outgrowth. Then an inch or two lower down the bowel the outgrowths infiltrated the wall and the surface was ulcerated, forming a typical adenoid cancer which occupied two inches of the bowel and contracted its lumen, so that the little finger could only just be passed through the stricture. In this cancerous growth the ulcerative process had perforated at one spot, but no faecal extravasation had occurred. The lower two or three inches of the rectum had been removed for cancer a fortnight before death. This portion was involved in a typical adenoid carcinoma, which in some parts fungated and in others was excavated by ulceration. The growth penetrated into the muscular wall of the bowel, and with much fibroid tissue filled up the space between the rectum and coccyx. Between this cancerous growth and the one in the sigmoid flexure the bowel was thickly studded with polypi which did not infiltrate the wall. On microscopical examination the polypi were found to be adenomatous. The gland tubes were very large and there was very little intertubular connective tissue. The columnar type of the cells was well marked.

² Diseases of the Rectum and Anus, 1890.

³ T. Smith: St. Bartholomew's Hospital Reports, 1887; Cripps: Transactions of the Pathological Society of London, 1882, p. 185; Handford: Transactions of the Pathological Society of London, 1890, p. 133; and THE LANCET, Jan. 21st, 1893 (two cases).

Handford, loc. cit., and my own case.

¹ The specimen was shown at the meeting of the Bristol Medical-Chirurgical Society, May 8th, 1895.

The glandular tissue growth was directly continuous with the mucous membrane of the colon, the submucous connective tissue passing into the growth as a short stalk. Some of the gland tubes where there was hardly any lumen looked rather like branches of a papilloma cut transversely, the centre of the gland tube being filled with granular material; but that they were not of this nature was shown by the fact that the periphery of the epithelial cells (the portion free from the nucleus) looked towards the centre, where the lumen was so marked in most of the tubes; and, moreover, there were no branching papillomatous processes to be seen in any of the sections (which were vertical ones through the whole polypus

Section of one of the polypi, showing its adenoid structure.
Half-inch objective.

and its attachment to the intestinal wall), so that the gland tubes could not be the depressions between such processes. The carcinoma of the lower end of the rectum was typically that of an adenoid cancer. Masses of columnar epithelium were seen invading the muscular coat of the bowel in addition to glandular outgrowths. In these epithelial masses the columnar type of epithelium could in most places be made out and the glandular character recognised.

Cases of disseminated polypi published elsewhere—An exceedingly interesting case of multiple polypi, in which carcinoma ultimately developed, is recorded by Mr. Thomas Smith.⁵ The patient was a man twenty-seven years of age in whom bleeding from the bowel began at the age of ten years, and he had had polypi repeatedly removed from the rectum. He came into the hospital at last with intestinal obstruction. Adenoid cancer of the lower part of the sigmoid flexure was found post mortem, and the rectum below contained a large number of polypoid growths similar to those removed during the patient's life. Above the seat of the cancer there were but few to be found, and only three or four in the ascending and transverse colon. The polypi are described as well-marked examples of the adenoid variety. Out of the family of six one brother and one sister were under Mr. Smith's care with a similar condition. Mr. Cripps records the case in his book as proving that after many years of innocent life one of the multiple polypi may take on malignant action and assume all the characters of adenoid cancer. Dr. Handford⁶ reports a case of disseminated polypi of the large intestine becoming malignant. There were 170 polypi of the structure of the normal mucous membrane of the part with proliferation of the gland tissue. At the middle of the transverse colon there was a "sessile polypus" about the size of a small walnut. The base of it was infiltrating the intestinal wall, and had given rise to a puckering stricture which would just admit one finger. There was also a stricture of the rectum due to adenoid cancer. The microscopic structure of both the "sessile polypus" of the transverse colon and the malignant growth in the rectum was identical; there were numerous spaces lined with columnar epithelium, with invagination of the wall into them. Mr. Dunn also reports⁷ a case of multiple adenomatous polypi removed from the rectum of a boy aged ten years. Dr. Norman Dalton records⁸ a case of multiple polypi of the whole of the large intestine. They occurred in a woman aged twenty-eight years.

Their structure was that of mucous membrane, with proliferation of gland tissue in some. Each polypus consisted of a stalk, which varied in length from two inches and a half downwards, and was rounded in some cases and flat in others. Nearly all the stalks expanded at their free ends, some being bulbous and others like a fringe. These extremities were mostly soft and bleeding. At the same meeting of the Pathological Society⁹ Mr. J. Hutchinson, jun., referred to a case which exhibited at the necropsy multiple polypi and numerous epitheliomatous ulcers side by side. Mr. Makins also referred to a case of a girl aged eighteen years who two years after the removal of several polypi from the rectum returned with intestinal obstruction which proved fatal, and post mortem well-marked columnar epithelioma was found. Thus the case which I now record makes the fifth in which disseminated polypi of the colon have been associated with malignant disease. Mr. Bowlby¹⁰ records a post-mortem examination on a man aged sixty-four years, whose colon was the seat of numerous polypi which on microscopic section were found to be composed of loose connective tissue; and Mr. Shattock¹¹ describes multiple polypi from the rectum of a child which were composed exclusively of lymphatic tissue. Van Buren in his book on the Diseases of the Rectum refers to a case recorded by Richet¹² of a man aged twenty-one years, from whose rectum 60 to 100 polypoid growths were removed. They consisted of hypertrophied rectal follicles and caused exhausting hæmorrhages.

It will thus be seen that the structure of these multiple polypi is generally adenomatous. Mr. Cripps describes the polypi in Mr. Thomas Smith's case¹³ as adenomatous, but his drawing seems to me to suggest rather the structure of papilloma. The difficulty in distinguishing between them is, of course, often great, as the spaces lined by columnar epithelium may be either gland tubes or only the depression between the papillæ in papilloma. In Mr. Cripps's picture we see the edge of the growth well, and although the processes to the left are very regular, those to the right are very like the processes of a papilloma. Dr. Handford¹⁴ remarks that Mr. Cripps's growth is quite different in structure from the adenomatous character of his own, and more resembles the type of intestinal villi than the Lieberkühn follicle. The distinction between adenoma and papilloma is very clearly described by Mr. Shattock in discussing the pathology of these growths in connexion with his own case already referred to.

Bristol.

ENTERIC FEVER AMONG EUROPEAN TROOPS SERVING IN INDIA.

By W. HILL CLIMO, M.D. Q.U. IREL.,

BRIGADE-SURGEON-LIEUTENANT-COLONEL, ARMY MEDICAL STAFF (RETIRED).

THE report of the Sanitary Commissioner with the Government of India for 1893 deserves the close attention of all who are directly interested in the welfare of our army in that country. It has twice formed the subject of articles in THE LANCET,¹ and deals with questions which I have for several years made a special study. The salient points on which I now propose to offer some remarks are—(a) the increasing admission-rate and death-rate from enteric fever of British troops during the year 1893 in comparison with those of the previous decade, being per 1000 of strength respectively 20 and 5.29 in the former, and 14.7 and 4.13 in the latter period; (b) the relative freedom of native troops from the disease; (c) its greater prevalence in Goorkha regiments as contrasted with other native corps; (d) the immunity of women and children in some outbreaks; and (e) the high death-rate of officers of the British service as compared with that of the native, the proportion being 11 to 1. Before entering on this discussion, however, I should like to make a few observations on the etiology of enteric fever in India. Up to 1889 various opinions were held. One was that the disease was associated with malaria; while another was that it was a developmental disease,

climatic conditions acting on the constitutions of young persons, and that the large increase of the admission-rate and death-rate was best accounted for by the larger supply of susceptible material (young soldiers) since the introduction of short service. This was the official view. Very comforting and very optimistic it was so far as the responsibility for cantonment sanitary conditions was concerned. In that year Colonel G. F. Young (now Deputy-Adjutant-General of the Bengal Army) wrote a pamphlet on Cantonment Sanitation, in which he clearly indicated the causes that were at work; while earlier in the year I had written a series of letters to the *Pioneer* under the *nom de plume* of "Medicus," pointing out how grievous was this sanitary failure. This I followed up by articles in the *Pioneer*, the *Times of India*, the *Indian Medical Gazette*, &c., and by pamphlets which were submitted through the Principal Medical Officer of Her Majesty's Forces in India to his Excellency the Commander-in-Chief and to the Government of India. I urged that enteric fever in India, as in temperate climates, was specific in origin and was caused by sanitary faults which poisoned the air, food, and water-supplies, &c., more especially the water. These views were received at first with hesitation, or were even opposed; but link by link the chain of evidence was completed, and now they obtain such a general acceptance that only by referring to the annual reports of the Army Medical Department can it be realised how different were the opinions which prevailed a few years ago. The Indian Medical Congress, which assembled at Calcutta during the last cold season, sanctioned the theory of the specific nature of enteric fever; while Professor Hankin's bacteriological investigations in reference to recent local outbreaks of the disease no longer permit the shadow of a doubt. In the article entitled "The Scourge of India: its Cause," which appeared in the April number of the *United Service Magazine*, I have endeavoured to impress these results on the public and on responsible officials. I have referred to the increasing admission-rate and death-rate of enteric fever among British troops in 1893 as compared with the average of the previous ten years, and I have stated that the death-rate of officers of the British and Indian services is in the proportion of 11 to 1. These facts are pregnant with meaning. In the articles above quoted I have pointed out that this can only occur through new factors coming into existence, and these, too, of our own making, resulting primarily from the removal of medical officers from regiments, whereby is caused both sanitary and medical failure—sanitary failure because the proper unit of sanitation is the regiment, and medical failure because in the present relations of the medical service to the army medical treatment (not the least important of which is the early recognition of disease) does not reach the sick until too late.

The explanation of the comparative immunity of native troops is that in childhood natives "have passed through conditions arising from exposure to the enteric poison which in after-life render them exempt from the disease." This opinion is shared by many civil surgeons in large practice, by native practitioners, and by hakims. The nature of their diet also protects native soldiers from the ravages of the disease as it attacks Europeans, and may even abort the disease, as most certainly it modifies and masks the symptoms. Goorkha soldiers suffer more from the disease than other native soldiers, because being keen sportsmen, and being quartered in the lower ranges of the hills, a meat diet is not infrequent with them. It is curious to remark that the higher classes of Mahomedans, who are always flesh-eaters, suffer more frequently from enteric fever than the Hindoos. Some few years ago I had the opportunity of investigating an outbreak of continued fever in a large Indian gaol, and of scrutinising the necropsies. In every instance there was inflammation of the ileum in patches, though the specific ulceration was wanting. No doubt the determining cause of local lesions is the nature of the food.

The comparative immunity of women and children is undoubted, and is another proof of the correctness of the views herein advocated. The habits and functions of women are for the most part favourable to the exercise of recuperative power, while those of the young soldier are absolutely antagonistic. In children diagnosis is difficult and the specific ulceration is always wanting; consequently much of the mortality of children in India from enteric fever is put down to other causes, such as diarrhoea, convulsions, or some other intercurrent complication. A child suffering from enteric fever and exposed to an Indian climate dies so

rapidly that there is no time to differentiate the disease, and death is ascribed to the most prominent symptom. This immunity of women and children is not limited to enteric fever, but exists also as regards cholera. What is the inference? There is domestic prudence as regards food-supplies and greater attention to cleanliness in the family as compared with the bachelor soldier in his barrack room, with his love of adventure and his frequent visits to the regimental "bazar," &c.

Almost every week the Indian mail brings the news of the death of some young officer from enteric fever. This death-rate is appalling; it demands careful discussion and inquiry. I believe that the difference in the death-rates of the officers of the two services is due to the fact that the British regiments no longer have medical officers serving with them, while native regiments always have. No doubt the introduction of the station hospital system has been most beneficial and tends to a higher professional standard; but I am convinced that the army will never derive the full benefit of this change until it is so worked that every corps has a medical officer of its own to investigate the origin of disease at the very outset, to superintend the hygienic conditions of the soldier, and to afford him medical treatment before it is too late.

Colchester.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PERSISTENT BRANCHIAL CLEFT OF UNUSUAL LENGTH; SUCCESSFUL REMOVAL.

By C. T. B. MAISEY, M.R.C.S. ENG., L.R.C.P. LOND.

A YOUNG woman aged seventeen years came to me on July 25th, 1894, complaining of a bad neck which had troubled her very much for the last three years. The previous history was as follows: A small hole had been noticed in the right side of her neck just above the collar-bone since birth, which had discharged a little sticky fluid without pain. Three years ago the hole closed up and a large abscess formed the size of an orange, which discharged itself, and it continued to fill up and discharge till the date of the visit. There was no history of any abnormality in the other members of the family. On examination a small scab was seen situated half an inch above the sternal end of the right clavicle and surrounded by old cicatricial tissue. On removing the scab I exposed a small ulcerated surface with a central opening about one-eighth of an inch in diameter. Running almost vertically upwards, backwards, and inwards from this central opening a large, hard, freely movable cord could be felt, about the size of a No. 12 catheter below, but gradually diminishing in size above and terminating about the level of the hyoid bone. I passed a probe three inches and a half and felt the end of it through the tissues in the floor of the mouth, but there was no internal opening. I advised her to have the cord removed, and the operation was performed on July 27th, my partner, Mr. J. Westmorland, kindly giving the anæsthetic. Having passed a director along the fistula, I made a longitudinal incision over it and dissected the tube out in its entirety with scissors. The upper part of the wound healed by first intention, the lower (in the situation of old cicatricial tissue) by granulation; the wound was soundly united at the end of the tenth day, and has remained so since. The tube was, complete, three inches and three-quarters in length, about the size of a No. 12 catheter below, and tapering above to a blind pointed extremity. On microscopical examination the lumen was found to be covered by a modified transitional-celled mucous membrane four cells thick; it was ulcerated in places. Below this was a submucous layer showing active cell formation and some inflammation. Mucoid glands were present in this layer. Extending into the submucoid layer were muscle fibres arranged longitudinally with the length of the fistulous cleft. The muscle fibres were mostly in bundles, but there were a few isolated fibres close to the mucous membrane. The fibres were striated. No cysts were seen in the wall. The points of special interest in

the case are, in my opinion: (1) its rarity; (2) its unusual length and somewhat unusual course; and (3) the complete success which has attended its extirpation.

Manchester.

AN UNUSUAL CASE OF THYROID DISEASE.

By J. HILTON THOMPSON, M.D. VICT.,

LATE SENIOR RESIDENT MEDICAL OFFICER TO THE CHILDREN'S HOSPITAL, PENDBURY.

RECENT observations concerning the functions of the thyroid gland make the following case of considerable interest. A young man aged nineteen years came to me some time ago with the following family history. The father was neurotic and criminal; the mother also was neurotic. His friends stated that his manner had been peculiar of late, but could not say in what respect. The patient complained of a feeling of fulness in the head and what he termed "funny feelings," followed by depression of spirits. I noticed that the neck-band of his shirt was unbuttoned; on drawing his attention to it he said that it was too small for his neck. I then examined his throat and found the thyroid gland considerably and uniformly enlarged. His face was slightly flushed and the pupils somewhat dilated. The patient was perfectly rational in his conversation. Bromide of potash in combination with liquor arsenicalis was prescribed. In a week the patient was in his usual health and the thyroid gland had returned to its ordinary size. Three months after I was called to see this patient again. I found him in bed in a state of intense excitement. Several of his friends were in attendance and had considerable difficulty in keeping him from hurting himself. When spoken to he answered rationally, but apparently with great effort. Every now and then he would have exacerbations of excitement, throwing himself about on the bed and punching his own head or trying to dash his head against the bedpost. When he recovered from one of these attacks he usually appeared to be very hungry, generally demanding hot buttered toast. The thyroid gland was much larger than during the first attack; the shirt-band would not button by one inch and a half. The face was usually flushed, but after the exacerbations was pale. There was no exophthalmos. There was no trouble with the excretions. Drugs had no effect. At the end of ten days I had him removed to the workhouse hospital. Whilst there he had two attacks. When he returned home he appeared to be in his ordinary health. The thyroid gland had shrunk to its normal proportions. During the following six months this patient had two slight attacks similar to the first described, and in each the thyroid gland was distinctly enlarged. I have never previously seen nor have I read of a case of this description. The temporary enlargement of the thyroid gland is the most peculiar feature. To me it appears probable that the increased size of the gland was the result of increased physiological action, the nervous symptoms that were such a prominent feature of the case being the result of poisoning by the large and unusual quantities of thyroid secretion thrown into the circulation.

Bolton, Lancashire.

THE DENTAL HOSPITAL OF LONDON.—We have received a copy of the thirty-seventh report of the Governors of this institution, from which it appears that the financial position of the proposed new hospital stands thus: probable cost of site and building £40,000, against which there may be set the estimated value of the site of the existing hospital, say, £15,000 to £20,000 (which, however, cannot be realised until the new building is completed); contributions paid or promised, £11,000; amount required, £14,000. To enable the committee to purchase certain freeholds the bankers of the hospital, Messrs. Barclay Ransom and Co., have considerably made further advances of money, and to them there is now owing £19,650. Having regard to the growing demands on the limited resources of the hospital and the absolute need for increased accommodation for patients, the managing committee consider that they are justified in making a very earnest appeal to the benevolent public and friends of the hospital to assist them to specially reduce this debt, so that the new building may be commenced with the least possible delay.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. BARTHOLOMEW'S HOSPITAL.

TWO CASES OF EXOPHTHALMIC GOITRE IN SISTERS, WITH MORBUS CORDIS AND A HISTORY OF RHEUMATIC FEVER IN BOTH; REMARKS.

(Under the care of Dr. SAMUEL WEST.)

THESE two cases well serve to bring the point to which it is desired to draw attention before the profession. Dr. Hector Mackenzie in his clinical lectures on Graves' Disease, which we published in *THE LANCET*,¹ writes: "Quincy and rheumatism are antecedent or coincident in a significant number of cases. Out of some forty cases I have noted quincy in nine and acute rheumatism in five. This agrees with the evidence of other observers." He refers to a previous paper by Dr. West on this subject.

CASE 1.—A young woman aged twenty-six was under treatment at St. Bartholomew's Hospital for severe palpitation, which had commenced at the age of eighteen. It came on somewhat suddenly, and was attended at the same time with protrusion of the eyes and enlargement of the thyroid gland. It was diagnosed then as "Graves' disease," and treated for some time. Great improvement followed, and for some years the patient had regarded herself as practically well. When seen she still presented all the signs of Graves' disease, having some exophthalmos, though to no very great degree. There was obvious, but not very marked, enlargement of the whole thyroid gland, with palpitation at times, fine tremors of the hands, and a general nervousness of manner and speaking. The heart's apex was one inch outside the nipple in the fifth space; the cardiac dullness was increased upwards and also to the right somewhat. A loud systolic apex murmur was audible at the apex and behind, so that the patient obviously had mitral regurgitation. She had had an attack of rheumatism five years ago, and though she repudiated the idea of "the fever" she was one week in bed, almost unable to move for pain, and was invalided for seven weeks.

CASE 2.—The patient, the sister of the former, aged twenty-eight, came under treatment for Graves' disease, from which she stated that she had suffered for eighteen months, palpitation being the first distressing symptom, but the protrusion of the eyes and the thyroid swelling were observed about the same time. She volunteered the statement that she had the same disease as her sister, and it was in consequence of the statement that her sister was sent for. The most conspicuous symptoms about her besides her exophthalmos were the nervousness of manner and the tremors. The thyroid gland was uniformly enlarged, and the heart-like her sister's, with the apex one inch outside the nipple line, and with a loud systolic apex murmur audible in the axilla and behind. She, too, had had rheumatic fever.

Remarks by Dr. WEST.—These cases present two features of interest—viz., first, the occurrence of two cases in sisters, and, secondly, the heart lesion and the history of rheumatic fever in each. In a paper communicated to the Medical Society of London some years ago I drew attention to the frequency with which rheumatic fever occurred in Graves' disease. In the fifty-six cases I then analysed its frequency was 11 per cent. This fact is of some theoretical importance, for when the question is discussed whether palpitation of the heart can ever produce organic lesion appeal is usually made to exophthalmic goitre, but if in 11 per cent. of the cases a history of rheumatic fever is obtained it is pretty certain that five or six of them at least will have morbus cordis. When this number is deducted from the cases of Graves'

¹ THE LANCET, Sept. 13th, 1890.

disease that develop morbus cordis an insignificant residue is left which is quite insufficient to prove the conclusion required.

ROYAL SOUTH HANTS INFIRMARY.

A CASE OF CEREBELLAR ABSCESS FOLLOWING SUPPURATION IN THE MIDDLE EAR, WITH A POLYPUS IN THE EXTERNAL MEATUS; REMARKS.

(Under the care of Dr. J. L. THOMAS.)

THE symptoms which are caused by the presence of an abscess in the lateral lobe of the cerebellum are subject to considerable variation, and this case shows how very slight may be the evidence of the condition even when the abscess is of considerable size; in fact, rigidity of the muscles of the neck appears to have been the only sign present which is usually recognised as of any importance, and it may be met with in meningitis. The combination of small cerebellar abscess with meningitis is not uncommon. The usual history of chronic ear discharge was obtained, and we would urge on the profession the necessity of impressing upon parents the importance of having discharges from the ear in children treated as soon as possible. The complications of otitis media are both numerous and of grave moment. For the notes of this case we are indebted to the house surgeon, Dr. W. Frier Purvis.

The patient was a girl aged fifteen, who was admitted to the Royal South Hants Infirmary on Nov. 29th, 1894. Her history was that she had had a purulent discharge from the right ear for several years. Her friends had not noticed that she was deaf. On Nov. 23rd she was suddenly seized with headache and vomiting, and was thought to be suffering from a "bilious attack." Since that day she had complained of pain in the frontal region, and had been very noisy and delirious, shrieking out and behaving in an extremely hysterical manner. At first the otorrhoea had ceased, but had come on again during the 27th and 28th. At the time of her admission, on the 29th, she was a very healthy-looking and well-nourished girl. She lay on her back with her knees drawn up and eyes half closed, and said that she could not see. She complained of intense pain at the back of her head, but shrieked out on being touched on almost any part of her body, complaining also of great pain even on moving her arms. There was no retraction of the head, but the muscles at the back of the neck were extremely rigid. There were no enlarged glands in the neck, and there was no hardness in the course of either internal jugular vein. There was a fetid purulent discharge from the right ear, in which could be seen a large polypus. The knee-jerks were normal. There was no optic neuritis. The pupils were equal and reacted to light. There was no strabismus or nystagmus, and no facial or other paralysis, but urine was passed into the bed. Her temperature was 104° F., the respiration 42, and the pulse 104. No physical signs of disease were discovered in the thorax or abdomen. She continued in a noisy, delirious condition all that day and night. On the 30th her condition remained unchanged, but oedema was noticed over the right mastoid process. It was decided to remove the polypus and to explore the mastoid cells. This Dr. Thomas requested Dr. Purvis to do. Ether having been administered the polypus was snared and the granulations were scraped out of the meatus. A semicircular incision was made behind the ear and the pinna turned forward. There was a well-marked posterior auricular spine, and the bone was gouged away at a spot whose centre was a quarter of an inch above and behind this. A little pus soon welled up, and the mastoid antrum was found to be full of offensive cheesy matter. This was all cleared out with a sharp spoon until fluid could be syringed through from the meatus, and *vice versa*. Bare bone could be felt at the bottom of the meatus, and the malleus came away. A fine drainage-tube was drawn through from the meatus to the wound by means of a thread tied on to a probe. The wound was then closed and dressed antiseptically. Later in the day the patient still continued to be very noisy and restless, and was only partially quieted by morphine. The temperature at 8 P.M. was 104.4°. On Dec. 1st the part was dressed and the wound syringed out. There was absolute paralysis of the muscles on the right side of the face. This had not been noticed on the preceding night. The patient

passed her urine in bed, was very noisy, and was only quieted by morphine. Her face was flushed and her breathing shallow. She remained all day in the same dorsal position, with the knees drawn up. The temperature varied between 101° and 103°. Some difficulty in swallowing was noticed. On the 2nd the wound was dressed; the patient's general condition remained about the same. On the 3rd the discharge on the dressing was very offensive. The general condition improved somewhat. She seemed to be more conscious during the evening, and heard better after a quantity of cerumen had been dislodged from the left ear. On the 5th she still remained noisy and was only kept quiet by morphine. She continued to pass all her urine into the bed, her bowels being kept open by enemata. The dressing was changed to boracic fomentations. The bromide mixture, which she had been taking without appreciable effect, was discontinued, as a profuse papular eruption made its appearance all over the body. Her voice was noticed to be getting weaker and her cry to be more moaning. The pulse was 100 to 130, the respiration 36 to 40, and the temperature varied between 99.6° and 102.4°. On the 8th the patient was definitely worse; the temperature varied from 100° to 102.8°, the pulse being 130, and the respiration 45 to 52. She swallowed with great difficulty. She was still restless, but much quieter. She gradually sank and died on the 10th. At the necropsy the body was found to be well formed and nourished. The operation wound was quite healthy. On removing the skull-cap the dura mater was found to be healthy, and there was no clot in the superior longitudinal sinus. Near the centre of the vertex the dura mater was slightly adherent to the brain by a small patch of thick, opaque, yellowish-green lymph. Elsewhere the surface of the hemisphere was smooth and shiny. The cerebellum was adherent to the posterior surface of the petrous portion of the temporal bone on the right side, and on freeing it a large abscess cavity was ruptured. This proved to be in the right lobe of the cerebellum, very near the surface. Its antero-posterior diameter was two inches, and it contained two or three drachms of extremely offensive greenish pus. The walls of the abscess were formed of pulpy, sloughy brain matter. This abscess did not appear to have exerted any pressure on the pons or middle lobe of the cerebellum. There was a little thick yellow lymph in the inter-peduncular space. The sinuses were all healthy. The posterior surface of the petrous bone was bare and rough. The mastoid antrum and other air cells, when opened up, seemed to be well drained from the operation wound, and the aperture in the bone was in a good position.

Remarks by Dr. PURVIS.—In looking back over the symptoms of this case there are several points presenting peculiarities. I think I cannot do better than take them one by one, following Dr. E. Deanesly in his remarks in THE LANCET of Dec. 8th, 1894. It must be remembered that slight meningitis was present. The abscess was distinctly an acute one, both in symptoms and morbid anatomy. The otorrhoea had been present many years. Deafness was certainly present, though to what extent it was difficult to say. Optic neuritis was definitely absent. Headache was very severe. Vomiting only occurred at the commencement of the illness. The temperature was raised throughout; there was no shivering. The pulse and respiration were markedly accelerated. The mental condition was very peculiar; the word "hysterical" best describes it, perhaps. There were great irritability and constant screaming and shouting. The patient was conscious at first, but not afterwards. There was no motor or sensory paralysis excepting that of the facial nerve, doubtless damaged at the operation. There was certainly hyperaesthesia at first. Rigidity of the neck was a marked feature all through, but the head was not drawn back. The reflexes were normal. The question of exploring the brain for an abscess was discussed, but the patient's condition was not sufficiently encouraging.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.—A meeting of the Council of this society was held on Thursday, May 9th, at their offices, 12, New-court, Lincoln's-inn. A satisfactory report of the financial state of the society was laid before the Council, and ninety-two new members were elected, including Sir John Russell Reynolds, Bart., President of the Royal College of Physicians of London, and several other leading members of the medical profession in London and elsewhere.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Adjourned Debate upon Dr. Semon's Paper.

AN ordinary meeting of this society took place on May 14th, Mr. HUTCHINSON, President, being in the chair.

The adjourned debate upon Dr. SEMON'S paper was reopened by Dr. STEPHEN MACKENZIE, who said that he endorsed the remarks of previous speakers as to the value and completeness of the paper. It had often been said that specialism tended to narrow the views of an observer, but the subject before them had been dealt with in a manner that was not indicative of cramped judgment. If Dr. Semon had confined himself to clinical relationship everyone would have been with him. Mr. Butlin had dealt with the subject with great lucidity, and had shown that if the narrower title had been adopted and a clinical and pathological relationship had been advocated there would have been a general concurrence with such a view. When one spoke of pathological identity it was difficult to know what was meant. Etiology was of paramount importance; for instance, peripheral neuritis might be due to diphtheria, or syphilis, or beri-beri, and these affections, while closely related clinically, were pathologically distinct and specific; there was a clinical relationship, but not a pathological identity. Etiology was the fundamental point in the classification of disease, and this was again well illustrated in the various manifestations of lead poisoning, such as dropped wrist, lead colic, and cephalopathy. If we came to consider microbes, the same thing would be found to hold good. *Staphylococcus pyogenes aureus* would be found to produce in the skin impetigo, boils and carbuncles, and that all were due to the same virus could be proved by cultivation. He repeated that while Dr. Semon had lucidly and usefully shown that the relationship was a close alliance he had not established a complete identity. Without bacteriological evidence one could not prove more than a relationship between these different examples of disease. Cases of acute inflammation of the larynx or pharynx, accompanied by oedema, swelling of the uvula, epiglottitis, tongue, or floor of the mouth, might be due to a condition excited by herpes. He had seen several such cases diagnosed as acute laryngitis or acute pharyngitis which were due to herpes, which view was proved by the concurrent or subsequent development of herpes on the face or elsewhere. In 1876 a patient was admitted into the London Hospital with cellulitis of the neck. There was a brawny, tender, and diffuse swelling in the floor of the mouth, which tilted up the tongue. A diagnosis of angina Ludovici was made. Deep incisions were made into the cellular tissue of the neck, but only a little serum was let out. The patient died three days later, and the laryngeal muscles were found to be studded with *trichina spiralis*, which were encapsuled and were present in other muscles. In 1884 a case was admitted into the London Hospital under Mr. Couper in which there was inflammation of the cellular tissue of the neck. Dyspnoea was marked and tracheotomy was performed, but a fatal result ensued. At the post-mortem examination acute laryngitis was found, with acute miliary tubercles in the lungs. He thought that the bacteriological evidence which had been brought forward weakened Dr. Semon's position, for it had been shown that almost any microbe might produce a suppurative inflammation, and that any inflammation from its character need not reveal the particular kind of microbe which produced it. In the presence of ignorance concerning such important matters as this it was futile to attempt to establish a pathological doctrine, and until complete bacteriological evidence was forthcoming we could not accept the view that these diseases were pathologically identical.

Dr. DUNDAS GRANT was prepared on clinical grounds to give a general support to the views put forward, but he would not be inclined to include angina Ludovici with the other diseases as pathologically identical, for cases of angina Ludovici were not identical amongst themselves. He had been much impressed with the great danger to life in these diseases, and they often proved fatal in spite of relief to any impediment to respiration which might exist. He gave the details of a case to illustrate this. In another case, which he admitted to hospital as a peripharyngitis, the patient

suffered from a succession of septic phenomena, there being first a phlegmon in the pharynx, then facial erysipelas, then a second attack of inflammation in the throat, followed by swelling in the right knee-joint and wandering patches of pneumonia.

Dr. LOVELL DRAGE said that he believed in the pathological identity of the various forms of septic inflammation of the throat. He related the case of a schoolboy aged ten years, who was suffering from an acute inflammation of the fauces and oedema of the larynx accompanied by high fever. Tracheotomy was performed, with immediate relief. Later the disease again advanced and the boy died from double pneumonia twenty-four hours after the operation. There was a catarrhal affection of the larynx prevalent in the district at the time, and other cases occurred in the same school, but these were checked in the early stage by antiseptic measures. He had in a previous communication tried to establish a certain direct continuity between different forms of puerperal sepsis, and he believed that these again were of the same class as the throat affection. In connexion with the influenza epidemic he had frequently noticed the occurrence of throat trouble, there being ulcerations of the lips, gums, fauces, and larynx. In his experience success in preventing the progress of the disease depended upon the opportunities that occurred of accomplishing early disinfection of the mouth and accessory cavities. For this purpose he had at first used strong solutions of boric acid, but later he had more success with a biniodide solution. In connexion with the subject under discussion he remarked that he had had a number of cases which went to establish a definite relation between autumnal diarrhoea and typhoid fever; he had noticed a progressive intensity of the diarrhoeal disease.

Dr. HILL maintained that in the cases grouped together there was merely a clinical resemblance and not a pathological identity; in fact, Dr. Semon had proved that the diseases were pathogenically non-identical.

Dr. KANTHACK said that Dr. Semon had opened up a most difficult subject, but he thought that the paper was true in almost its entirety. Dr. Semon had claimed that these diseases were different stages of one pathological process, which he proposed to call septic inflammation. He himself had investigated four of these cases bacteriologically. The first was one of angina Ludovici, which arose after a severe tonsillitis which was probably diphtheritic in nature; in this he found streptococci. The second case, also one of angina Ludovici, followed gingivitis from carious teeth. In this case *staphylococcus pyogenes albus* and *aureus* were found. The third case was one of pneumonia complicated by inflammatory oedema of the larynx; in this a pneumococcus was found. The fourth case occurred in a woman who was admitted into St. Bartholomew's Hospital, and she aborted and died. At the time of death there was found a phlegmonous inflammation of the pharynx and larynx and a condition of general septicæmia. In the spleen, neck, and larynx streptococci were found. It should be remembered that there was a great difference between bacteriological identity and pathological identity. For instance, in ulcerative endocarditis there was great diversity bacteriologically. In different cases at least twelve different organisms had been found. The organisms in these affections of the neck belonged to the so-called pyogenic group, and there was a difference between pathologists and clinicians which to a great extent was due to the endeavour to fit modern ideas into old frames. The old text-book ideas about septicæmia and sapræmia were not founded upon good bacteriological ground; it was taught that sapræmia was septic intoxication and that septicæmia was septic infection, whereas in both cases infection was present, in the one case saprophytic and in the other parasitic. His own opinion was that in all cases of septicæmia which recovered no micro-organisms would be found in the blood. He had examined erysipelas bacteriologically and he confirmed Jordan's observations. He did not always find the streptococcus of erysipelas in these cases; this showed that the disease might be due to different organisms which were pathologically and clinically identical. The term "specific" was avoided by bacteriologists, for some diseases appeared to be only produced by a combination of different kinds of bacteria, such as streptococcus with staphylococcus in erysipelas. Until we found out the importance of such symbiosis it was necessary to be careful in applying the word "specific" to an organism. Everyone now agreed that the *staphylococcus pyogenes* and the *staphylococcus* of erysipelas were identical and could not be distinguished from each other. Some of these

organisms would produce on inoculation a local erysipelas, and others a general infection; some would have no effect on mice, while others would prove virulent towards mice. When once a streptococcus had become attenuated it was difficult to bring it back to virulence. The pneumonia streptococcus usually produced septicæmia, rarely erysipelas, and more rarely nothing at all on inoculation into the ear of a rabbit; though all three varieties would produce pneumonia, yet they differed in their action on the tissues, and this might depend partly on the local tissue reaction and partly on constitutional disturbance. Organisms could not be classed as different because they produced suppuration, for suppuration was not essentially different from inflammation. He thought that as far as present pathological evidence went Dr. Semon was right in his main contentions.

Mr. R. W. PARKER said that there were two chief points and one subsidiary point in this paper—the non-specificity of the microbe, the identity of all forms of inflammation, and the abolition of the present nomenclature with the substitution of a common term. He joined issue on each of these points. Reason led him to think that these microbes gave rise to special forms of disease, and if two organisms coexisted then a mixed form of disease resulted. In bacteriology the doctrine of this year became the heterodoxy of the year following, and this, he thought, applied to much of the evidence now produced. Bacteriology was studied under altogether artificial conditions, and the results obtained by cultivation in artificial media could not be analogous to those produced in the human body. He believed that these inflammatory processes differed essentially amongst themselves. If a case of erysipelas were left in a surgical ward it would be certain to spread to the other cases; but, on the contrary, a case of œdema of the glottis behaved quite differently. The difference lay really in the nature of the inflammation and not only in its degree of severity. The names in common use clinically were as useful as those of the children of a family; they served to distinguish the individuals of a group, they were different names for different kinds of inflammation.

Dr. SEMON, in reply, said that he was neither surprised nor discouraged at the opposing opinions which had been expressed, nor did he believe that the immediate verdict would be the ultimate one. The difficulties, he thought, were artificial, and he claimed only for his idea that it was a working hypothesis. When he spoke of pathological identity he meant that one and the same process took place in a group of diseases which differed *inter se* clinically. An inflammation might be serous, or purulent, or fibrinous, or gangrenous, and the two extremes appeared to differ entirely from one another, but clinically they could be shown to be mere transitions. In all the cases he had grouped together there was a violent exudation into the tissues, accompanied by rigors, fever, malaise, sweat, &c., and they were not different processes because they owned a different avenue of infection. The different bacteria produced the same pathological processes, and the several organisms were practically interchangeable with one another when they got into the tissues. He was aware that views identical with his own were being promulgated by other observers abroad. He could not support Mr. Lockwood in his demand that identity should mean identity of tissue, for if that definition were accepted we should be landed in a difficulty in the cases of gumma and tubercle of different organs. He hoped to live to see the day when the text-books of surgery would give in one great chapter all the septic inflammations classed together.

MEDICAL SOCIETY OF LONDON.

Annual General Meeting.—The Diagnosis of Retro peritoneal Sarcoma.—Series of Operations on the Stomach.

THE annual general meeting of this society was held on May 13th, the President, Sir WILLIAM DALBY, being in the chair.

The report of the Council was read and adopted. Allusion was made to the losses the society had sustained in the deaths of its treasurer, Mr. Arthur Durham, and of Sir George Buchanan, a former Lettsomian Lecturer. In point of numbers and finance the progress was most satisfactory, and the completion of the new buildings was announced.

Mr. C. B. LOCKWOOD read a paper on the Diagnosis of Retro-peritoneal Sarcoma. He said that, although this disease was rare, everyone who performed many laparotomies

was sure to meet with examples. He had met with this embarrassing condition in two cases, in neither of which would an operation have been performed if the nature of the disease had been diagnosed. In the first case the signs pointed apparently to a solid ovarian tumour. The abdomen was greatly distended, and when it was opened a tumour like a thick-walled cyst appeared, but nothing escaped by the trocar, and a quantity of semi-gelatinous fluid was removed by the hand. The relations of the tumour could then be ascertained. It grew behind the peritoneum into the folds of the mesentery, and had lifted up the left colon which lay in front of it. The mesenteric vessels traversed its substance, and its removal was impossible. It was a myxo-sarcoma, and extended behind the peritoneum from the brim of the pelvis to the diaphragm. It did not seem to spring from any of the great organs, and probably originated in the retro-peritoneal connective tissue. The second case had also many of the characters of an ovarian tumour, but its diagnosis seemed very doubtful. The abdomen was not quite so distended as in the first case. The tumour grew behind the peritoneum, lifted up the intestines, and had distended and nearly obliterated the mesentery. The patient recovered from the operation after a severe illness. In the early stages of these growths diagnosis might not be difficult, but their onset was insidious, and the patients were not seen by the surgeon until the abdomen had become distended. The anomalous character of the tumours ought, however, to have aroused suspicion, and in each of these cases the abdominal resonance must have been altered owing to the distribution of the intestines over the growth. In the last case the tumour was sometimes dull and sometimes resonant, presumably according as the intestinal coils were distended or collapsed; but unfortunately the significance of this sign was not appreciated.—Sir HUGH BEEVOR referred to a case which had come under his observation while Registrar at King's College Hospital. The patient was a man aged thirty-two years, who twelve weeks before admission had his left testis removed. He had noticed a swelling of the abdomen five weeks later, and emaciation had commenced. On examination a swelling was found in the upper part of the abdomen extending two inches below the umbilicus and most prominent on the left side. There was resonance over a small area in the epigastrium, which was only noticed on one occasion. The patient died suddenly. A movable nodule was found in the left iliac region, which proved to be a secondary sarcomatous growth in the great omentum. A mass as large as a cranium was found posteriorly, the transverse colon crossing the front of the growth. The stomach was pushed high up towards the left. The growth was noted to be red and friable, and there was a small nodule in the liver. Though this case was repeatedly examined in the ward, with a view to discovering the position of the transverse colon, that tube could never be mapped out by resonant percussion.—Dr. SNOW said that the condition described by Mr. Lockwood would exist in other retro-peritoneal tumours—renal, pancreatic, or lymphatic. These growths probably arose from congenital rudiments of the Wolffian body, from which sprang the rhabdo-myomata. On palpating over deep-seated malignant abdominal growths he had noticed a peculiar emphysematous crackling.—Mr. LOCKWOOD, in reply, said that these cases could not be extremely rare, as he had met with two in four years. His remarks applied only to cases of advanced growth, with much distension of the abdomen. In the case in which a necropsy was performed there was nothing to indicate the locality of the origin of the growth.

Mr. ALLINGHAM read a paper on a Series of Operations on the Stomach, which is published in full in another part of our present issue.—The PRESIDENT hoped that more details would be given with regard to the object accomplished by these operations. Was there not only a prolongation of life but a lessening of suffering whilst these poor patients with malignant disease were obliged to live? Was it worth while, under such conditions of life, to make the attempt to prolong that life by weeks or months?—Mr. LOCKWOOD discussed the condition of the patient as regarded his comfort after a successful operation; he had a general impression that in some cases of gastrostomy the after-condition was one of greater comfort, while in others the patients did not like the artificial opening. Of three cases of gastrostomy which he had seen, two died in a short time, and the other—a young woman with a tight stricture of the œsophagus from swallowing corrosive poison—found the opening so

unpleasant that she allowed it to close. Operation should not be delayed until the patients were moribund, but should be undertaken when they ceased to take soft solid food. In some cases of cancer of the œsophagus the patients reached their end with reasonable comfort by the wearing of a soft œsophageal tube.—Dr. SNOW inquired if Mr. Allingham had performed Alberti's operation, a valvular opening being made through the skin and the stomach drawn through this so that the artificial opening lay over the seventh rib. Many malignant strictures of the œsophagus might at first be mistaken for simple fibrous growths, as the neoplasm might be of the atrophic variety. He asked if medical treatment had been tried in the advanced cases, rectal feeding being combined with the administration of opium and the local use of cocaine.—Mr. ALLINGHAM, in reply, said the majority of his patients had expressed a sense of great relief after the operation, and especially the cases of gastro-enterostomy. Regurgitation might be prevented by making a small opening into the stomach. He believed that there were more cases of fibrous stricture than had hitherto been suspected.

CLINICAL SOCIETY OF LONDON.

Absence of Abdominal Muscles in an Infant.—Extensive Degenerating Nævus of Bladder.—Gastric Ulcer treated by Laparotomy.

AN ordinary meeting of this society was held on May 10th, Mr. LANGTON, Acting President, being in the chair.

Mr. R. W. PARKER described the case of an infant in whom some of the Abdominal Muscles were absent. The abdominal wall was as thin as parchment. Except along the middle line, where the upper and lower extremities of the rectus could be distinctly felt, the anterior abdominal wall contained no muscle; it was extremely flaccid, and permitted manual examination of each one of the viscera. The muscles of the back appeared to be normal. The infant died from collapse and emphysema of the lungs. A detailed account of the necropsy, made by Mr. Theodore Rake, was appended.—Mr. LANGTON said that a child was admitted into St. Bartholomew's Hospital with an area of gangrene of the anterior abdominal wall, the removal of which led to exposure of the intestines. On examination of the removed parts the whole thickness of the abdominal wall was found to consist of skin, subcutaneous tissue, and fat, there being no muscle present.

Mr. ARBUTHNOT LANE related a case of Extensive Degenerating Nævus of the Bladder in a child aged three and a half years, who was admitted into St. John's Hospital, Lewisham, on Oct. 10th, 1894. Two years previously the child commenced to pass bloody urine, and at times large flat clots; this condition varied in degree, the blood being at times so abundant as to cause the urine to resemble fluid blood. On this occasion the hæmorrhage had been so profuse and so prolonged that the child appeared to be in great danger. There were scattered about the anus and buttocks a few small patches of degenerated nœvoid tissue, and their presence had led Mr. Leopold Burroughs and Mr. Stokes, whose patient the child was, to diagnose the condition of the bladder as being also nœvoid. The bladder was distinctly large as felt above the pubes and by the rectum. Mr. Lane opened the bladder above the symphysis, when large nœvoid masses, some as large as grapes, protruded through the incision. They were mostly soft and bled very readily, while others were hard and apparently cystic. Almost the whole of the mucous surface was affected, one or two narrow strips alone remaining normal. The arrangement was such that it seemed unwise to attempt to include masses of the growth in ligatures. Not seeing any way of treating the condition without much risk Mr. Lane closed the incisions into the bladder and skin, intending to interfere subsequently should styptics applied locally not have the desired effect. Strychnine was used for this purpose. For some unexplained reason the child's condition changed after the operation, the hæmorrhage practically ceased, and her colour and weight improved very rapidly. Occasionally she passed a little coloured urine at long intervals. Mr. Lane considered the case of sufficient rarity to bring before the society, as he expected to find an adenomatous or papillomatous tumour or tumours.—Mr. PARKER said that he had never seen a nœvus which had spontaneously bled, though many nœvi underwent spontaneous ulceration.—

Mr. PEARCE GOULD said that a case of nœvus of the rectum and another of nœvus of the œsophagus were on record, both of which had bled.—Mr. GORDON BRODIE said that a case of nœvus of the male breast had been published by Mr. Bland Sutton which had been the seat of spontaneous hæmorrhage.—Mr. HURRY FENWICK said that nœvus of the bladder was very rare, the only specimen with which he was acquainted being in St. George's Hospital Museum. No case of villus of a child's bladder was on record, the tumours being mostly myxo-sarcomata. Indeed, all the cases described in literature and all the specimens preserved were so classed, with the exception of two specimens, one of which was in University College Museum and the other in St. Thomas's Hospital Museum.—Mr. LANE very briefly replied.

Mr. L. A. DUNN read notes of two cases of Gastric Ulcer treated by Laparotomy. One, a girl fifteen years of age, was admitted into Guy's Hospital on May 19th, 1894. She had suffered from gastric disturbance for some four months previously. The day before admission she was suddenly seized with intense pain in the abdomen and vomiting. On admission the pulse was 150 per minute, the respiration 33, and the temperature 101° F. The abdomen was resonant, not very rigid, and a hyper-resonant area was discovered on the left side of the epigastrium, reaching half-way up the sternum. Dr. Pitt diagnosed perforating gastric ulcer and ordered nutrient enemata and other medical treatment, but as the case did not improve he asked the surgeon to explore the abdomen. This was done at two o'clock on the morning of May 21st. The abdomen was opened in the middle line by a long incision reaching from a little below the umbilicus nearly to the ensiform cartilage. Upon separating some adhesions binding the liver to the abdominal wall some opalescent fluid escaped, and when the liver was pulled upwards and the stomach repressed some coffee-coloured fluid with gas and a clot of coagulated milk escaped. The perforation, which measured one-third by one-quarter of an inch, was found on the anterior wall of the stomach, near the small curvature. It was with great difficulty brought into the wound and closed by a double row of Lembert's sutures. The abdomen was flushed and closed in the usual way. The patient progressed favourably for thirteen days, when at 1 P.M. on June 3rd she vomited and cried out with intense pain. The pulse, which before was 88 per minute, rose to 160. Her face was pinched, and there was great restlessness. As no improvement took place it was decided at 9 P.M. to again open the abdomen as it seemed probable that a fresh perforation had occurred. This was accordingly done along the left costal margin, where nothing was found save a distended stomach attached to the abdominal parietes by a few recent adhesions. These were separated, and the wound was closed. After this recovery was rapid and uninterrupted. The second case was that of a woman aged twenty-eight, under the care of Dr. Hale White, admitted on June 4th, 1894, with well-marked symptoms of gastric ulcer, who had been treated in the usual way till June 29th, when at 6 P.M. she suddenly screamed out with pain in the epigastrium, vomited half a porringerful of greenish fluid, and became intensely collapsed. As it seemed almost certain that perforation had occurred, laparotomy was performed at midnight. The anterior surface of the stomach was exposed by a median incision. Nothing unusual was found as regarded adhesions, gas, or free fluid. The stomach was fairly distended, and no gas escaped on moderate pressure, so the wound was closed in the usual way. Vomiting continued after the operation and the patient succumbed in four days. The necropsy revealed neither peritonitis nor extravasation of gastric contents. A large gastric ulcer was found, through the floor of which, since post-mortem digestion had taken place, the gastric contents could be made to pass on squeezing the sides. The wound was quite healthy and healing.

Mr. SILOOCK also described two cases of Perforating Gastric Ulcer. In one the edges were sutured, and the case ended fatally. In the other, formation of reparative adhesions took place, and laparotomy with drainage was followed by recovery. In Case 1 a woman was admitted to St. Mary's Hospital under the care of Dr. Lees on April 10th, 1894. The history of her illness and her condition on admission led Dr. Lees to the conclusion that she was suffering from a gastric ulcer which had "perforated." Mr. Silcock opened the abdomen, and on examination of the stomach found a small perforation admitting the end of a large probe amidst the remains of recent adhesions of lymph which glued the anterior wall of the viscus to the anterior abdominal wall.

A few bubbles of gas and a little clear fluid neutral in reaction escaped on opening the peritoneum. There had been no further extravasation of stomach contents. The necrotic edges of the ulcer were excised and, thus freshened, were enfolded by Lembert's sutures. A drainage-tube was so disposed as to carry away any discharge from the neighbourhood of the perforation, the stomach and parts involved in the operation being sponged over with corrosive sublimate solution and the wound dressed antiseptically. The patient was fed by nutrient enemata. Despite every care, she died on April 25th (fifteen days after the operation) from septicæmia due to the accumulation of pus between the left lobe of the liver and the diaphragm, behind the stomach, and above the spleen (subphrenic abscess). All efforts to drain this abscess failed. Post-mortem examination showed that the perforation had soundly healed. Mr. Silcock contrasted this case of fatal issue with the following (Case 2), pointing out that the woman was comparatively healthy, the perforation recent and easily got at, the surgeon requisitioned at the earliest possible moment, and the closure of the perforation a success surgically. In Case 2 a woman aged twenty-four was admitted into St. Mary's Hospital under the care of Dr. Cheadle on April 7th, 1895. She was evidently suffering from acute gastric ulcer, and was treated, therefore, in the usual way. Seven days after admission she became suddenly worse, and symptoms of perforation were present. At Dr. Cheadle's request the abdomen was opened by Mr. Silcock, a small quantity of turbid serum of neutral reaction together with a few bubbles of gas escaping on incision of the peritoneum. A wide band of fibrinous adhesions bound the anterior surface of the stomach to the under surface of the left lobe of the liver. The perforation being evidently in the midst of these well-developed reparative adhesions, and the ulcer being of unknown extent, they were left alone, a drainage-tube being placed in position and the wound closed. The operation was followed by immediate relief, and the patient made an uninterrupted recovery. Mr. Silcock thought that the issue in this case showed the inadvisability of interfering with adhesions when these shut off the perforation from the general peritoneal cavity, and mentioned the possibility of infecting the general cavity of the peritoneum had this been done, and of opening up a perforating ulcer so large that it would have been difficult or impossible to have dealt with it adequately by suture.

Dr. LEES related four cases of this kind. The first was one of subphrenic abscess coming on after not very acute gastric pain. The diagnosis was not easy from localised empyema. Mr. Pepper with some difficulty managed to reach the collection with a trocar, giving exit to some pus, but he failed in an attempt to reach the abscess by following up the line of puncture. On making an incision he found that the left pleura was opened, and he therefore allowed some time to elapse for adhesions to form. Though there was marked pneumothorax, within thirty-six hours all the air was absorbed. Two or three days later there was a sudden attack of hæmorrhage which proved fatal. Only a very limited examination was permitted, but they made out a large, old, firm-edged, whitish ulcer on the posterior wall of the stomach. The second case was very acute. The operation was done within forty hours of the rupture by Mr. Page. The case had been published, but he remarked on the fact that the perforating ulcer was high up on the anterior wall and was discovered without much difficulty. It was sutured, and post mortem the union was quite firm. The third case was also acute and was operated upon by Mr. Pepper within a few hours of the patient's admission. He had no difficulty in finding the ulcer or in sewing it up, but the patient died. Post mortem they found a very large ulcer situated on the superior border of the stomach and extending on to both the anterior and posterior walls. The ulcer on the anterior wall had perforated and was sutured, the suture being perfect after death, but they also found a perforation behind, which had caused death. The fourth case was one of those related by Mr. Silcock. Although the ulcers in the first three cases were easily found, it was almost always necessary to break down some adhesions to get at them, and the inflammatory fluid had a tendency, whatever the situation of the ulcer, to make its way upwards above the left lobe of the liver beneath the diaphragm, and to collect there in a cavity of its own. This suggested whether it might not be possible to drain such collections from behind without going through the pleura. If this were possible he thought it would be good practice either in addition to the suture of the ulcer or possibly even in

preference to suture. He pointed out that the adhesions were often fairly strong and the ruptured ulcer high up, and under these circumstances an intervention on these lines might prove satisfactory. He recalled another case in which a patient with a history of gastric ulcer complained of marked epigastric pain and tenderness, and where very great relief was derived from the application of ice to the epigastrium, which at once controlled the vomiting.—Dr. TURNER said he had long entertained the idea of reaching these abscesses through the ribs posteriorly. He had examined one or two cases of subphrenic abscess post mortem and had found that excision of the eighth rib would certainly open the pleura, but it would be below the margin of the lung and would tap the abscess quite well. With free drainage one might possibly adopt this course without much fear. It was sometimes practically impossible to distinguish between subphrenic abscess and localised empyema, but the treatment suggested would cover both conditions. In one case of his own, that of a girl aged twenty-one years, the symptoms came on gradually with an attack of pain forty-eight hours before. She was sick once or twice, but the symptoms were not very urgent; there was, however, the absence of liver dullness. She developed a slight amount of dullness at the left base, but she ultimately recovered after a long illness. Another case was that of a woman thirty years of age, who walked to the hospital, with the history of having twenty-four hours previously had pain in the epigastrium extending to the left shoulder. There was slight rigidity in the upper part of the abdomen, and she presented the same absence of liver dullness, the pulse and temperature being normal. She was kept in hospital three months, and finally she developed an area of dullness continuous with the spleen, extending two inches upwards. Then there appeared an inflammatory lump on the right side of the chest, which was opened, giving exit to bile-stained pus. The patient died, and post mortem the liver was found to contain numerous abscesses, as also did the spleen in its upper part. There was pus in the base of the pleura, but not below the diaphragm. There was a cicatrised ulcer in the anterior wall of the stomach and the splenic vein was filled with pus. He pointed out that the case which was admitted with the more acute signs recovered, while the other, apparently of a less severe type, succumbed.—Mr. WATSON CHEYNE mentioned a case under his care about a fortnight since, the patient being a girl aged seventeen with distinct symptoms of perforating ulcer having occurred forty-eight hours before. He opened the abdomen and at once came down upon fluid and upon the ulcer. The aperture was limited by firm adhesions all round, so he left the wound open, closing it a week later, but two days after that she sank and died. Post mortem he found a large abscess above and behind the stomach in the neighbourhood of the spleen. In another case, in which there was a swelling in the left hypogastric region, distinctly fluctuating, it was opened and the patient recovered.—Dr. HALE WHITE pointed out that the prognosis in these cases stood in no discoverable relationship to the gravity or otherwise of the symptoms. In his case the rupture occurred while the patient was in bed and was operated on within six hours, yet she died. Moreover, no trace could be found of the ulcer and very little evidence of peritonitis. It occurred to him that it might be practicable to distend the stomach with gas in these doubtful cases in order to decide the existence of a perforation. He had since had another case which showed the great difficulty of diagnosis. A woman was suddenly attacked while in bed with pain in the stomach, and on admission she showed symptoms of general peritonitis. There was nothing in the previous history to lead one to suspect gastric ulcer, but there was persistent vomiting, which was immediately relieved on washing out the stomach. She died quite suddenly, and post mortem he found a perforated ulcer firmly adherent to the under surface of the liver, so much so that the adhesions had not yielded notwithstanding the washing out of the stomach. He did not think a surgeon could have got at that ulcer. He also recalled the case of a man with an appendix which measured seven inches in length and passed under the third portion of the duodenum. It suppurated, and laparotomy was performed, but the abscesses burst and the patient died. That would have been an excellent case for an operation from behind.—Dr. ROSE BRADFORD said he had seen two cases of the kind at University College Hospital illustrating some points suggested by Mr. Silcock. The first was that of a girl seen within eight hours of the accident, who was operated on

within an hour. She recovered perfectly, the only complication being thrombosis of the femoral vein. The other case was that of a young girl seen within twenty-four hours of the perforation. The usual incision gave escape to a large quantity of fluid. She did well for a fortnight, but the temperature never returned to normal and she succumbed to an abscess at the base of the left lung. Both patients displayed the absence of liver dulness. He asked whether this symptom persisted, or whether, in consequence of the absorption of the air, the liver dulness reappeared after a while. He remembered a case of abscess at the upper surface of the right lobe of the liver on the under surface of the diaphragm. The patient presented the characteristic pain in the shoulder. Mr. Treves opened the abscess by an incision below the last rib, followed by the insertion of a long drainage-tube, and the patient recovered.—Dr. HALE WHITE added that in his case the accident happened on a Wednesday, and the patient was brought to the hospital on the following Sunday. The liver dulness was then normal, so presumably the gas had been absorbed.—Mr. DUNN, in reply, pointed out that in the patient on whom he had operated twice absence of liver dulness was well marked on both occasions. If he had tried an opening from behind in either of these patients, so exhausted were they that he believed the result would have been disastrous.—Mr. SILCOCK, in reply, said it was impossible to open from behind without going through the diaphragm and opening the chest, and he would certainly not like to do that. Moreover, in such cases there was usually nothing to guide one. In respect of the tympanitic area, he did not know in virtue of what law the gas accumulated over the liver. If it were because, being lighter, it came to the surface, one would expect the tympanitic area to change its place on shifting the patient. This, however, was not the case in his patient, although there were no adhesions to keep the gas in place.

HARVEIAN SOCIETY OF LONDON.

The Surgery of the Rectum.

A MEETING of this society was held on May 2nd, the President, Sir JOHN WILLIAMS, Bart., being in the chair.

Mr. BERNARD PITTS read a paper entitled "Remarks on the Surgery of the Rectum," which we publish in full in another column.

Mr. EDMUND OWEN thought that Mr. Pitts' simple and practical paper would tend to correct the erroneous idea that the lower portion of the alimentary canal had a special and peculiar histology and pathology. He regretted, however, that it had not dealt more fully with the surgery of developmental errors of the rectum and anus, a subject on which Mr. Pitts could give much information. Mr. Owen alluded to the case of an infant whose hypoblastic and epiblastic portions of the rectum were perfectly formed; but as no meconium had been passed the monthly nurse had persistently and ineffectually administered castor oil. The introduction of the little finger into the anal aperture showed that nature had omitted to break down the horizontal septum between the anal and the pelvic portions of the bowel, and as soon as this septum was perforated a copious motion was passed. Persistence of the fibrous circumference of such a partition was likely to give rise to lifelong trouble by causing recurrent attacks of constipation. In such cases inguinal colotomy might be the only alternative to ineffectual attempts at dilatation. He was glad that Mr. Pitts was opposed to the wholesale adoption of colotomy in cases of cancer of the rectum. The subjects of this disease might, under careful dietetic restrictions, enjoy years of life before colotomy was really necessary. When, however, they began to suffer from obstruction of the bowel colotomy should promptly be resorted to.

Mr. HERBERT ALLINGHAM said that he quite agreed with Mr. Pitts that excision of fissure with suture was unnecessary. Whitehead's operation for hæmorrhoids he considered quite unnecessary, as it required much time. The bleeding was severe, and if the mucous membrane tore away from the stitches great constriction resulted; in fact, some of the worst forms of anal stricture he had seen were preceded by Whitehead's operation. He much preferred Salmon's operation by ligature with incision. The rapid dilatation of stricture of the rectum he considered to be a very

dangerous mode of treatment, as the stricture constantly ruptured into the peritoneum. The best mode of treatment consisted in very gradual dilatation or division of the stricture by many small incisions. It was most unnecessary to perform colotomy on all patients with cancer of the rectum. That operation should only be employed when the symptoms were very severe and when palliative treatment failed to give relief. He had seen many patients who had declined to submit to colotomy when it was recommended, and who had by palliative measures been able to go on for three or four years before colotomy at last had to be performed.

PATHOLOGICAL SOCIETY OF MANCHESTER.

The Relations between the Structure of the Liver and Certain Pathological Lesions.—Curious Cutaneous Products.—Fractured Cervical Spine.

A MEETING of this society was held on May 8th, Professor SHERIDAN DELÉPINE, the President, being in the chair.

Professor DELÉPINE gave an account of his views on the Structure of the Human Liver. He demonstrated by means of preparations and micro-photographs that in the classical or vascular lobule of Kiernan there are evidences of an arrangement of the columns of liver cells which are incompatible with the notion that the arrangement of the epithelial elements is entirely subordinated to that of the veins. He proved that by taking certain precautions it is possible even in the normal liver to see that the columns of liver cells are tubes with very narrow lumina branching from terminal bile-ducts. This branching is evidenced by a divergence of the columns from lines extending between adjacent portal vessels (portal lines of divergence). This arrangement proves clearly that Sabourin's views regarding the biliary lobule are wrong. Professor Delépine exhibited a number of microscopical preparations of lesions which showed clearly the grouping of columns of liver cells round terminal bile-ducts and not round the so-called intralobular veins—e.g., (1) starving liver, showing clearly portal and hepatic lines of divergence, and the branching of columns of liver cells from portal spaces towards hepatic veins; (2) fatty liver with typical grouping of infiltrated cells in the form of alternate nodes on the sides of portal vessels and surrounding Glisson's capsule; (3) parenchymatous hepatitis, followed by almost universal atrophy of epithelium and the almost total transformation of the columns of liver cells into tubes containing cylindrical casts of bile pigment; (4) epithelioma of bile-ducts, causing accumulation of bile pigment within the intralobular and intracellular bile canaliculi; (5) livers in various stages of digestion, showing the grouping of iron and glycogen in various parts of the lobules, and other preparations.

Dr. WAHLTUCH showed some curious Coloured Cutaneous Products obtained by friction of any part of the body of an unmarried woman aged fifty-five years. She had suffered for six years, since her menopause, from periodical attacks of irritation of the skin, which were relieved by warm baths, and were attended by the separation, by rubbing with towel or hand, of coloured, fluffy, and curly masses. There is no skin affection otherwise to be noticed. The microscopic examination shows each small roll to be composed of: (1) a thick covering of epithelial cells; (2) thin, tangled hairs, some long and colourless, and a few broken up and red, blue, green, or brown; (3) irregular, pigmented masses, red, blue, brown, or black; (4) a few starch corpuscles; and (5) hardly any trace of fat.

Mr. J. W. SMITH and Mr. J. G. CLEGG showed the Cervical Spine from a case of Fracture of the Atlas and Axis, with pulping of the spinal cord, in which life was prolonged for several hours by artificial respiration.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on May 7th, Dr. S. JOHNSTON, President, being in the chair.

Dr. CHAPMAN showed a specimen of Fractured Spine in a child aged two years. The child was dead when admitted into the Bradford Infirmary. On post-mortem examination

a fracture of the fourth dorsal vertebra was found. There was blood effused outside the membranes of the cord. The spinal cord was torn across, but the membranes were not injured.

Dr. KERR showed a patient who had been trephined for Tuberculous Meningitis. The patient was a boy with a tuberculous family history, whose health began to fail in January, 1895. Until March he attended school. He then began to be sickly, a squint which he previously had become more marked, and his temperature was 99.5° F. Dr. Kerr saw him at this time and diagnosed tuberculous meningitis, the symptoms being headache, constipation, talking in sleep, and the meningitic cry. There was, in addition, great restlessness, stiffness of the muscles of the neck, cerebral vomiting, and optic neuritis in the left eye. Dr. Wood trephined the middle fossa, the dura mater was incised, and a small quantity of fluid escaped. The brain did not pulsate. On passing a trochar into the lateral ventricle no fluid was obtained. A drain of silkworm gut was passed towards the base of the brain and the wound was dressed. The patient made a good recovery, having no pain after the operation and being less irritable. The drain was removed on the seventeenth day, after which the wound healed soundly, and within a month the patient was able to play cricket.

Mr. HORROCKS showed a patient with Double Hydrocele.

Dr. MAJOR gave a demonstration on the Management of Primary Batteries for Medical Purposes, pointing out the importance of the practitioner being able to recharge the cells himself, and that frequent use was the best way of keeping the batteries in order.

EDINBURGH OBSTETRICAL SOCIETY.

The Influence of the Removal of the Ovaries on Metabolism.—Vesico-Vaginal Fistula.—The Biddenden Maids.—Exhibition of Specimens.

A MEETING of this society was held on May 8th, Dr. A. H. FREELAND BARBOUR, President, being in the chair.

A paper on the Influence of the Removal of the Ovaries on Metabolism, by Professor E. CURATULO and Dr. LUIGI FARRULLI of Rome, was communicated by Dr. J. C. WEBSTER. These researches were intended to elucidate the cause of the benefit received in osteo-malacia by the removal of the ovaries. Different theories have been advanced, but these have not been supported by indisputable facts scientifically proven. Febling's hypothesis is that a stimulus is removed which acts on the vaso-dilator nerves of the bones, causing passive hyperæmia, with an accumulation of carbonic acid, and consequently reabsorption of earthy salts. Petrone's studies tend to demonstrate that the good effects upon the disease are only due to the anaesthesia—supposing it to destroy the fermentum nitricum—rather than to the removal of the ovaries. It seems probable that the changes which take place in the metabolism after castration in healthy animals would throw light upon this subject. It is well known that castrated animals grow fat, but there has been no scientific investigation into the cause of this accumulation or into the changes in the metabolic activity of respiration, or into the composition of the urine after the operation. This last item was taken up as a preliminary research. The experiments were made on bitches which were kept on a constant diet before the castration, so as to have an almost constant average of nitrogen and phosphates in the urine. After castration it was observed that the quantity of phosphoric anhydride discharged through the urine is considerably and for a long time diminished. Thus in a bitch before castration there was a daily average excretion of 9.93 gm. of nitrogen and 1.50 gm. of phosphoric anhydride; after the operation the average amount of nitrogen remained the same, while the phosphoric anhydride had diminished to 0.75 gm. This statement was based upon daily researches for eighty-five days after castration. This decrease took place with considerable rapidity after the operation. In another bitch when the wound had healed in three days, and the daily examination of the urine continued after six days, a decrease in the discharge of the phosphoric anhydride was immediately noticed. This fact has an important bearing on the subject of osteo-malacia. Its pathogenesis is still unsettled, but there is no doubt that there is a considerable decrease of the earthy salts composing the bones, so that these lose their natural solidity

with consequent bending where there is the greater strain. The phosphates in the urine are partly derived from the food and partly from the waste products of tissues containing phosphoric organic substances, and mostly from the discharge of the earthy phosphates contained in the bones. These animals were kept on a similar diet before and after castration, so that the decrease in the excretion of phosphoric anhydride must depend on a diminished oxidation of organic phosphorus in the tissues. This storage of organic phosphorus in the system would allow of its combining with calcium and magnesium, and its accumulation in the bones as phosphate of calcium and magnesium. We admit that the ovaries have, like the other glands of the animal economy, according to the general doctrine of Brown-Séguard, a kind of internal secretion and that they continually secrete a product into the blood, the chemical constitution of which is unknown, capable of facilitating the oxidation of the phosphoric organic substances which supply the material for forming the salts of the bones. By the removal of these glands there must be a greater retention of organic phosphorus and consequently of earthy salts in the form of phosphates until the skeleton resumes its normal solidity. This theory may be extended to what concerns the waste or combustion of the fat, and this may also explain the well-known phenomenon of fat accumulation after castration, and perhaps also the similar condition very often noticed at the menopause and in sterile women.

Dr. J. A. C. KYNOCH read notes on a case of Vesico-vaginal Fistula resulting from an Unusual Cause. The patient had suffered from prolapse of the vagina with some cystocoele for several years, and had not received any treatment. While descending a stair covered with ice she slipped and slid down several steps. Previous to this she had been working in a standing posture for several hours, and had not passed urine for the same time, and she felt the prolapse protruding from the vulva. She experienced a good deal of pain about the vulva, and there was some hæmorrhage, which continued for three days. Pain occurred with micturition. She was confined to bed for a few days, and on rising noticed some dribbling of the urine. The incontinence was only slight at first, afterwards constant. On examination a marked prolapse of the vagina was found, with a fistula of the size of a sixpence about an inch from the vaginal orifice. This was cured by two operations. It was evident that the prolapsed portion had been injured by the fall, with consequent ulceration and formation of a fistula.

Dr. J. W. BALLANTYNE gave notes on the Biddenden Maids. These were twins born joined together in the year 1100 at Biddenden, in Kent. There was union at the hips and at the shoulders. From the existing data it is difficult to determine whether their shoulders were joined or whether the arms were joined at the elbows, as one illustration depicts. Dr. Ballantyne remarked on its being a unique case from a teratological point of view. They lived to the age of thirty-four, and when one died the other was advised to be separated from her sister by dissection, but she refused, saying: "As we came together, we will also go together," and in six hours afterwards she also became ill and died. By their will they bequeathed some land to the churchwardens for the benefit of the poor, and on Easter Sunday many small cakes are given away, each with their effigy stamped thereon. Professor Simpson suggested that their apparent union at the shoulders may have been due to their walking about with their arms round each other's neck.

Dr. FELKIN showed an Antiseptic Sponge Holder. Dr. FORDYCE exhibited a Fœtus which had evidently been retained for about three months after death. Two specimens of Fœtus Compressus were shown by Dr. J. W. BALLANTYNE and Dr. BUIST, Dundee.

PRESENTATIONS.—Mr. George Daunt, L.R.C.P., L.R.C.S. Edin., of Ilchester, on the occasion of his leaving the district has been the recipient of a splendid field-glass from his friends as a token of their esteem and regard.—Dr. Wm. D'Ojly Grange of Moffat, Dumfriesshire, on his leaving that town after a residence of nineteen years has been presented by his friends, in testimony of their friendship and regard, with a costly chronograph gold watch, bearing the following inscription: "Presented to William D'Ojly Grange, Esq., M.D., as a mark of esteem from numerous friends on the occasion of his leaving Moffat. April 30th, 1895." Mrs. Grange has been the recipient of an elegant évergéne, on which is inscribed: "Presented to Mrs. D'Ojly Grange from her friends in Moffat. April 30th, 1895."

Reviews and Notices of Books.

The Dyspepsia of Phthisis: its Varieties and Treatment. By W. SOLTAN FENWICK, M.D., B.S. Lond., M.R.C.P. London: H. K. Lewis. 1894.

MORE than once in the pages of this lucidly written monograph the author reminds us that comparatively little is heard nowadays of the alliance between pulmonary phthisis and gastric derangement, which was dwelt upon with considerable emphasis by writers on both sides of the subject a generation or more ago. It is not that their observations were faulty. There is ample proof in this book to the contrary, showing, as it does, how frequent are dyspeptic troubles in the phthisical, both antecedent to and concomitant with the manifestation of tuberculous disease. But we presume that the explanation of the comparative silence on the matter may be found in the fact that according to our present conceptions of the origin of tuberculosis the existence of such disorders has been relegated to a less significant place in the etiology of phthisis. And it seems to us that Dr. Soltan Fenwick, who has ventured to break this silence, is himself convinced that the rôle of dyspepsia as an antecedent to tuberculous phthisis is nothing more than one factor in the production of enfeebled nutrition that tends to lessen the resistance of the subject to the inroads of the bacillus tuberculosis. It is indeed striking that so many victims of the pulmonary disease should, prior to its onset, have suffered from dyspepsia, but that there is nothing specific in the type of the gastric intestinal disorder itself is manifest from the descriptions that are given of its symptomatology. Moreover, the consideration that, after all, phthisis attacks only a minute portion of the great army of dyspeptics proves that the connexion is not one which merits much consideration in etiology. It must not be supposed, however, that a monograph on the subject is not needed, or that it will fail to be serviceable in practice. On the contrary, we believe that the author has done good service by his very careful study of the subject, and especially by the prominence given to the importance of treating disordered digestion as a serious element in the history of those whose life-history or environment disposes them to tuberculous disease. Moreover, he has made a distinct contribution to our knowledge of the nature of the lesions that are met with in the stomach in advanced phthisis, which throws light upon the association between the pulmonary and gastric affections.

The opening chapters of the book are devoted to these questions of pathology and morbid anatomy. The frequency of the occurrence of dilatation of the stomach in the phthisical is first alluded to. The mammillation of the mucous membrane so characteristic of chronic catarrh, and long since described, is attributed to contraction of the intertubular connective tissue; but a similar appearance is produced by enlargement of the solitary glands, which, as the author subsequently states, may form follicular ulcers. Amongst the forms of ulceration he has met with, it may be especially noted that he has found some due to lardaceous disease of the vessels, mainly in the pyloric region. The great rarity of tuberculous ulceration of this viscus, as contrasted with that of the intestine, is attributed to the inhibitory action of the gastric juice upon the bacilli and also to the scantiness of lymphoid tissue in the stomach. The condition characteristic of phthisis, which is described from a careful examination of fifty cases, is one of interstitial inflammation, leading to destruction of the gastric tubules and more or less diffuse cirrhosis. In a certain proportion of cases there is also lardaceous degeneration. The chronic gastritis is found to be most marked in the more advanced cases of phthisis with excavation, and

the conclusion arrived at is that it is excited by the absorption of toxic substances formed within the pulmonary cavities. As regards chronic ulcer, it is shown that although present in a certain proportion of cases of phthisis the gastric affection has no special relationship with the latter—no more than cancer has. Having disposed of these pathological questions, the author next takes up the clinical side, treating in turn of the dyspepsia of strumous children, the dyspepsia which is apt to precede the development of pulmonary tuberculosis, the dyspepsia of the early stages of phthisis, and the dyspepsia of advanced phthisis. The characters and course of each variety are described in a satisfactory manner, and the measures of treatment detailed. Although, naturally, the subject can hardly be said to be novel—for dyspepsia in its atonic as well as in its "irritable" forms is only too familiar to practitioners—he has succeeded in imparting much useful information, both on the general topic and on that specially defined, which cannot fail to be of service.

The Pathology of Insanity: the Means and Methods of its Study. By W. J. COLLINS, M.D. Lond., J.P., L.C.C. Reprinted from *St. Bartholomew's Hospital Journal* February, 1895.

THE above is the title of a paper read before the Abernethian Society on Nov. 29th, 1894, and reprinted in pamphlet form from the *St. Bartholomew's Hospital Journal* for February, 1895. Agreement will be felt at the outset with Dr. Collins's statement: "The pathology of insanity is a realm in itself, at once vast, obscure, and in part untraversed"; and he disarms criticism by unreservedly disclaiming his qualifications for the task of treating the subject. His position, however, on the London County Council brings him into contact with asylum work, and it is not to be expected that so energetic a member of the medical profession will be contented to ignore the need of making constant inroads into this vast and obscure realm. He discusses the reasons for the "relatively backward state of the pathology of insanity compared with the well-cultivated fields of other areas of disease," laying due stress on the difficulty of investigation and the proportionate littleness of lesion with the magnitude of the malady.

The paper is mainly an inquiry into "what is being done by way of pathological investigation at the County asylums of London with their 11,000 lunatics; how this compares with work done elsewhere; and what proposals have been or are being made, with a view to stimulate further advance." As a result of a series of questions put to the Medical Superintendents of the London county asylums by a subcommittee of the late London County Council, of which Dr. Collins was chairman, the conclusions were arrived at (among others which are fully set out in the paper) that the post-mortem examinations as conducted at present are not exhaustive in a pathological sense, though adequate for ascertaining the causes of death, that research beyond routine post-mortem examination would be likely to lead to some improvement in the treatment of the insane, and that one pathologist should be appointed for all the London county asylums and should be provided with adequate laboratory accommodation for physiological and physical examination and for microscopical and chemical investigations.

Dr. Collins ends his paper with a statement of the points in his opinion to be "borne in mind by those who shall in the future seek to explain and illumine this dark continent of mental disease." Some of the points he enunciates seem distinctly to encroach on what was laid down by the subcommittee in its recommendation to the Council—viz., that the pathologist "should not have charge of, nor interfere with, the clinical treatment of the patients, and his work

must in no way conflict with that of the medical superintendent." How, if this is carried out, he can "duly and wisely" observe mesmerism and electro-biology, ascertain the effects of lead, mercury, arsenic, silver, coal gas, &c., on the mind, and the temporary and abiding effects of heat and electricity, is not stated. Of the pathological work already done in asylums little notice is taken, though the Yorkshire and Lancashire asylums are kindly taken by the hand in one line. If English asylums were referred to at all, at the very least the pathological section of Bevan Lewis's "Text-book of Mental Diseases," embodying the results of the labour of years, should have been mentioned. That more work needs to be done in the County of London, however, will be denied by no one, and it is to be hoped that the Council will very soon appoint their pathologist.

Die Thierischen Parasiten des Menschen: ein Handbuch für Studierende und Aerzte. Von Dr. MAX BRAUN, O.O. Professor für Zoologie und Vergleichende Anatomie, und Director des Zoologischen Museums der Universität Königsberg. Zweite völlig umgearbeitete Auflage. Würzburg: Adalbert Studer's Verlagsbuchhandlung. 1895. (*The Animal Parasites of Man: a Manual for Students and Practitioners.* By Dr. MAX BRAUN, Professor of Zoology and Comparative Anatomy, and Director of the Zoological Museum of the University of Königsberg. Second edition, fully revised. Würzburg: Adalbert Studer. 1895.)

ONE of the most striking facts of modern science is assuredly the great change that has been effected in the conception of the rôle of the parasite as a causal factor in disease. This conception now dominates the whole range of infective diseases, and is giving rise to entirely new and fruitful lines of research, of which as yet we can but dimly perceive the issue. But setting aside this large class it is remarkable how much our knowledge of the part played by animal parasitism has widened within the past few years. No one can peruse the pages of the compendious handbook before us without being astonished at this fact. In many directions there is opened up quite a new field of inquiry, a field by no means yet exhausted. No longer have we to confine our attention to the few species of intestinal worms and of cutaneous parasites which have been so long familiar. The parasite is to be found in the blood and the tissues, and in the constituent cells of the latter. It exerts an influence which is often of the greatest importance to the functions of the body as a whole, although in the animal scale the organism itself may be of the lowest rank. Indeed, almost in proportion as the parasite is low in the scale so accordingly does its action seem to be fraught with more danger to the life of its host. This, of course, is not strictly true, since many of the protozoal organisms that have been discovered of late years are as harmless as such higher animals as trichinæ, filariæ, and echinococci are harmful. Human parasites have now been found among the protozoa, platyhelminthes, nematelmintes, acanthocephali, hirudines, and arthropoda. In the first-named group there are several amœbæ, of which the most important is the amœba coli, whilst isolated instances are given of amœbæ in the buccal cavity, in the urinary organs, and in necrosed bone (Kartulis). Among the sporozoa there are the gregarinidæ, of which the coccidia form the chief, several species being found in the tissues and organs of the body. The malarial parasites are described as forming the order of hæmosporidia. Several infusoria have been found in man, many discovered more than fifty years ago, such as trichomonas, lumbilia, and the balantidium coli. After a full description of each of these classes the book deals in turn with the more familiar parasites, each section being introduced with a general description of the morphology and life-history of the class. There is not so much detail or historical matter as in Leuckart's classical work, but it is evident that the author has spared no

pains to make his treatise complete and useful. The references to the literature of the subject are abundant, and we do not think that any material point has escaped mention.

Petit Manuel d'Antiseptie et d'Asepsie Chirurgicales. Par FÉLIX TERRIER, Professeur à la Faculté de Médecine de Paris, Chirurgien des Hôpitaux, Membre de l'Académie de Médecine; et M. PÉBAIRE, Ancien Interne des Hôpitaux de Paris. Félix Alcan, Editeur. Avec 70 Figures dans le Texte. Paris: Ancienne Librairie, Germer, Baillière et Cie. 1893.

IF there is one thing more than another in which our French confrères excel it is that power of concise and accurate diction which characterises such a large proportion of their medical and surgical descriptive work. The little book before us is marked by all the good features which are inseparable from the work of writers in whom these characteristics are marked, whilst it exhibits comparatively few of the weak points which are sometimes associated with such conciseness; the descriptions are sufficiently full to bring out most of the points on which the authors wish to lay stress, and in many instances little of importance has been omitted. The writers give what they have to say under four headings: (1) the Antiseptic Method; (2) the Aseptic Method; (3) what they call a Mixed Method; and (4) Application of Antiseptic and Aseptic Principles to Special Regions and Organs.

We should like to point out that under the first two headings there is drawn an artificial distinction which certainly does not exist, and which Lister himself would strongly decry. It is perhaps somewhat unfortunate that, owing to the fact that Lister's method received its name when the method of working was slightly different from the present mode, the term "antiseptic" should have been used; but now that we have the name it is somewhat to be regretted that issues should be confused by the introduction of the term "asepsis," for, after all, whatever methods are employed the battle of the surgeon is just as much *against* septic infection as ever it was, and it is only because the methods of carrying on this war have been somewhat improved that the new term has crept in. Lister's whole teaching goes to show that his object was to obtain an aseptic condition with as little injury to the tissues as possible, and therefore with the exclusion as far as possible of the agents that he used from the action on the tissues; and, whether the instruments are sterilised by heat or by the use of chemical reagents, and whether the water used for washing out the wounds is sterilised by means of heat, filtration, or carbolic acid, the end aimed at is the same in all cases. It therefore leads to misconception as to the principles at the root of Lister's method when this artificial distinction between antiseptics and asepsis is made. With this criticism we may pass on to indicate the contents of the work by saying that it is a small book of 180 pages, in which are described the various methods in vogue for the treatment of wounds, and for the preparation of apparatus and material for carrying on antiseptic surgery under the best possible conditions. The whole question of the sterilisation of instruments and of dressings, the preparation and sterilisation of drainage tubes, and the disinfection of the skin, of the hands of the surgeon and of the water used for the washing out of the wounds, are all clearly and succinctly given; whilst in the chapter on Regional Disinfection we have descriptions of the methods and apparatus used to obtain asepsis of the skin, of the eye, nose, ear, and mouth, of the pharynx, stomach, intestinal and urinary canals, and of the genital organs in obstetrical cases. Altogether the work is very complete and is very fully illustrated, and we strongly recommend it to anyone who wishes to have in small space and for ready reference the main points to be attended to in the antiseptic treatment of surgical cases.

THE LANCET.

LONDON: SATURDAY, MAY 18, 1895.

It still seems improbable that the Midwives Registration Bill will pass through Parliament in the present state of parties and of public business; but it is obvious that the second reading of it in the House of Lords and the very calm and judicious speech of Lord BALFOUR OF BURLEIGH bring the whole question more clearly into public view than has ever been the case before. Our readers will judge for themselves from the report of the discussion in the House of Lords. Lord BALFOUR, who has charge of the Bill, described the evils of the existing system, under which any woman, however dirty, intemperate, or ignorant, may call herself midwife without check on her practice and without responsibility to any authority. Illustrations of such a system are of weekly occurrence, and have led all responsible people to ask for a remedy. The Home Office, the General Medical Council, juries and coroners, and the medical and the lay press have been all agreed on the subject. Lord BALFOUR did not enter into any elaborate comparison of the prevalence of preventable puerperal death and disease in Great Britain, where there is no legislation to regulate the practice of midwives, and in foreign countries, where such legislation is the rule. He contented himself with the statement that a large proportion of the humbler classes are attended by midwives who have practically no training, and that the results are disastrous and often tragical. He made much of the unanimous demand for a remedy for this state of matters, and he maintained that the Bill provided such a remedy. He protested his own interest in the question and declared that it was created by looking into the facts and being convinced of their urgency. He said he had consulted all persons likely to be informed on the subject, including the President of the General Medical Council. He noticed three objections to the Bill—first, that it would introduce a new class of medical practitioners; secondly, that natural labour could not be defined; and thirdly (and he touched delicately on this last objection, scarcely spoken, but obviously held by some), that the Bill would take away "business" from the medical profession. The profession will thank him for the mere justice which he did to it in saying that their lordships would not believe for a moment that if the Bill would really diminish death and suffering the medical profession would oppose it. In concluding a speech which must make a great impression from its very moderation he said there were only three courses open—to leave things alone, to prohibit midwives altogether, or to pass some such Bill as the one he proposed. Lord THRING accepted the arguments of Lord BALFOUR, but objected to certain details. Lord PLAYFAIR, speaking for himself and for the Government, expressed sympathy with the objects of the Bill, but thought there

were difficulties which would require consideration. He asked for time in order that the Government might suggest amendments that would enable them to support the Bill.

We shall best make a present contribution to the discussion of this question by impressing on each party in the contest the strength of the opponent's case. The medical profession is deeply interested in this question. It in the long run is responsible for the lives of lying-in women, and no legislation can alter this fact. The midwives contemplated by this Bill or any such Bill are mere subordinate helpers to work under it. It has a right to insist on a clear line of demarcation between itself and its subordinates, and on a definite limitation of the distinction between medical qualifications and others. It is justified in emphasising the fact that the Act of 1886 brought midwifery into line with medicine and surgery, and that by that legislation the pretence to exercise midwifery has a semblance to the pretence to exercise medicine and surgery, which it had not before. On the other hand, those who offer such an unyielding opposition to this legislation must remember that its advocates have made out a strong case for it, that the General Medical Council is committed to it, that it has been recommended by a Select Committee of the House of Commons, and that no language has ever overstated the misery and the mischief which arise from the continued existence of a class of midwives which has no analogue in any other branch of nursing, medical or surgical. If any surgeon dealing with an open wound were approached by a nurse of the GAMP order he would refuse to operate till she left the room. Similarly it is indispensable that such persons should be ejected from the lying-in rooms of the poor. The time has come when there must be a reconciliation of conflicting views. If the midwife is to be registered it must be made clear that she is in no sense a medical practitioner. The opponents of the Bill have a right to make terms with its advocates; but they will scarcely be well advised or consult the dignity of the profession if they offer an uncompromising opposition and refuse to rescue poor women from the perils of their present obstetric arrangements. We have always maintained, and shall continue to do so, that theoretically every lying-in woman should have the means of procuring, if necessary at the public expense and by an emergency provision, the aid and advice of a medical man; but ours is a practical profession, and we have to adapt our theories to the fact that a large number of women are too poor to be attended by medical men, and that the risks arising from attendance by midwives may be much reduced. We trust that the interval which will now elapse owing to Lord BALFOUR'S compliance with the request of the Government for time will be utilised by each party for the purpose of considering this question from the other's point of view, and in well weighing the opinions of those to whom they may be opposed. We are not only a practical profession, but a humane one, and some means must be devised for abating this misery in the lives of the poor.

On Thursday, the 9th inst., Lord PLAYFAIR, on behalf of the Government, brought in a Bill for the reconstitution of the present University of London, and it was

read for the first time. The details of the Bill will be discussed at the second reading, which will probably take place next week. Lord PLAYFAIR said that the Bill only consisted of four clauses, and that it was drawn on the general lines laid down in the recommendations of the Royal Commission. A statutory commission would be appointed to frame statutes and ordinances in accordance with the general principles of the scheme, but with powers to modify details after hearing evidence from the existing University or any of the other bodies or persons affected. It would, therefore, appear that practically another prolonged inquiry will be held, as objections to many parts of the scheme have already been expressed by some of the institutions which will form constituent Colleges in the University. In particular, it is urged that the Academic Council, which is the keystone of the scheme, is much too small and that the number of its members must be increased. If this be done, its relations to the Senate and to the Faculties will require reconsideration and modification. A special clause has been introduced into the Bill to safeguard the interests of non-collegiate students—whom Professor SILVANUS THOMPSON so unwisely designated as "the country blacksmiths and cobblers." But the difficulties are much greater than the supporters of a reconstruction of the existing University appear to think. The Commissioners themselves foresaw these difficulties, and could recommend nothing more definite than the following regulation: "That the final examinations for the first degree, for internal and external students respectively, will, if not the same, represent the same standard of knowledge, and will be identical so far as identity is consistent with the educational interests of both classes of students." In practice it will be found that the non-collegiate student will be placed at a disadvantage as compared with the collegiate student, and the degrees will represent different values.

At the meeting of Convocation on Tuesday last this point was emphasised by many speakers, and especially by Mr. BOMPAS as the chief reason for rescinding the resolutions in favour of the reconstruction of the University which were passed in January last, but his motion was defeated by 238 votes against 117. It is obvious that the majority of those who attend Convocation are in favour of the recommendations of the Royal Commissioners. This is probably due to the fact that London graduates and teachers largely attend the meeting and vote, but that they do not really express the views of the whole body of graduates was most conclusively shown by the result of the voting for the election of a Fellow of the University. This does not require a personal attendance, and the poll was a very heavy one, there being 1231 votes for Dr. NAPIER and 733 for Mr. COZENS-HARDY. This is a clear proof that a large number of the country graduates are opposed to the change, for Mr. COZENS-HARDY is one of the most influential advocates of reconstruction, while Dr. NAPIER is in favour of there being two Universities in London—viz., a Teaching University separate and distinct from the present examining institution and the existing University on its old lines. The results of the voting on Tuesday do not presage the passing of the Bill.

At the presentation on Wednesday, Lord HERSCHELL endeavoured to prove that those who held that the changes suggested would lower the degrees, or that they would injuriously affect non-collegiate students, were making unwarrantable assumptions; but he adduced no new arguments except that the present standard had been created by the examiners, who were largely London teachers. But this influence has hitherto been carefully safeguarded by combining with them, especially in the Faculty of Arts, provincial teachers, and in many cases non-teachers, or teachers from schools and colleges in no way connected with the University. This is an entirely different proceeding from teachers examining their own pupils in their own courses of instruction. We regret that Lord HERSCHELL unfortunately forgot, in his anxiety to defend his position towards the scheme, to refer to the medical aspect of the question.

No one can read the Factories and Workshops Bill and watch the proceedings of a Committee of the House of Commons in reference to it without wondering what are the proper functions of a department of the State and what of a local authority. The welfare of the workman in his occupation is now regarded as the concern of the former, and in his home of the latter. There can be no logical justification of this division; it must, and no doubt does, depend upon the fact that for the purposes of employment the workpeople are combined—for their home lives they have no combination. It is true that distinction is made between their employment in factories and in workshops—if in the former they are under the care of the Secretary of State, and if in the latter of the local authority; but this arrangement is the outcome of necessity, due entirely to the inability of a central department to supervise innumerable workshops and workplaces and not to any desire of the Secretary of State to leave to local authorities a duty which he would undertake if he could. Mr. ASQUITH has, in fact, indicated sufficiently clearly his own view of the situation, and there is no doubt, were he able, he would follow the workman to his dwelling-place if this be used for his work. Throughout the Bill we find the employment of the central rather than the local authority which characterises all factory and workshop legislation. In regard to ill health caused by lead or arsenic poisoning, or anthrax, if due to occupation there is to be notification to the factory inspector and not to the medical officer of health, who receives notice if the workman contracts a dangerous infectious disease in his own home. The medical officer serves an authority not always credited with independent action, and the inspector an authority less likely to be subject to local influence. Whether this governing principle of the Bill is sound, whether if abandoned to the local authority the workman would not eventually make his influence felt on that body, can be only matter for speculation. Everyone wishes the workman to be protected in his occupation, and we accept therefore the principle and may discuss the provisions of the Bill on their own merits.

We note in the first instance that it is proposed to incorporate in an Act of Parliament a requirement of a specified amount of cubic space for each person employed in a factory

or workshop. The amount which is thus demanded is 250 cubic feet, with addition under special circumstances, and for this amount we must at once admit there is no physiological justification. It is, no doubt, a compromise between the physiologist and the employer, who, to carry on his business, cannot pay more than a limited rental. Hitherto the cubic space to be provided, whether in common lodging-houses or in houses let in lodgings, has been left to be defined by by-law, and we doubt the expediency of giving a statutory sanction to an amount so small as that stated. It can only be justified if 250 cubic feet is a distinct advance upon the amount generally provided. The proposal as to lead and arsenic poisoning and as to anthrax we have already referred to in one sense, but it must also be considered in another. It suggests that the medical officer of health is not concerned with disease wherever caused, but only when it is not caused, by an occupation. This raises a very large question and demands the serious consideration of the Secretary of State and of the Local Government Board. It is the suggestion of a principle that must in the end be detrimental to the workpeople, and, inasmuch as it puts a limitation to the scope and usefulness of the medical officer of health, tends to prejudice the future of this office.

We observe that the Bill only concerns itself with these diseases when caused by an occupation, and the scope of the Bill, we presume, necessitates the adoption of this course; but we wish it were otherwise. Their notification is the proper forerunner of measures for their prevention, and we doubt if any more salutary lesson could be given to a sanitary authority than to require the notification of all cases of lead poisoning which might result from the supply by that authority of lead-poisoned water. The difficulty which underlies the proposal of notification of lead poisoning is that it is a chronic malady, and hitherto notification has been limited to certain infectious diseases running an acute course and lasting but a few days or weeks. How this difficulty is to be overcome we do not profess to say. The Bill now before Parliament will give opportunity for experience to be gained of any difficulty attending the notification of a chronic malady.

The proposals of the Bill as to bakehouses are admitted by Mr. ASQUITH to be inefficient. It was evidently not considered in the first instance to be the occasion for a radical change in the law dealing with these places. This Mr. ASQUITH proposes to amend, and his proposals will be awaited with interest. Some of the amendments of which notice has been given are impracticable, but they indicate a praiseworthy desire to deal with a subject which has been of late years much before the public. Among other useful provisions is that which prohibits an employer from knowingly putting out wearing apparel to be made in a building in which there is a case of scarlet fever or small-pox, and which Dr. FARQUHARSON properly proposes should be extended to include other dangerous infectious diseases, a proposal which does not appear to commend itself to the Government; another is that which will give facilities to local authorities to know of places occupied by out-workers; and again another which requires lavatory accommodation to be provided in every factory or workshop in which lead, arsenic, or other deleterious substances are used.

Interest will undoubtedly centre in the proposals of Sir JOHN GORST to prohibit the employment of children under the age of twelve years in any factory or workshop, and in a similar proposal of Mr. JOHN BURNS which would extend the prohibition to thirteen years. There is, of course, much to be said in favour of this principle, and the whole question will, we presume, turn upon the practicability of its application. The discussion on this point will excite great attention.

Annotations.

"Ne quid nimis."

THE HEALTH OF LORD ROSEBERY.

THE simple matter of a speaker stopping for some thirty seconds in the middle of a speech has been made the text for a host of unfounded rumours. We have authority for stating the following facts. The Prime Minister had had a very fatiguing day; after the usual morning's work he attended the Drawing Room and had a succession of important interviews until a late hour in the afternoon; he then entertained twenty people at dinner, being in excellent health and spirits. Not having originally intended to take any part in the proceedings at the National Liberal Club he had prepared no set speech, and therefore (as will happen to the most practised orator when speaking extempore), being very tired, he lost for a moment the thread of his argument. Receiving a clue from Mr. Campbell-Bannerman he went on with his speech as if nothing had happened. His lordship is now cruising with Lord Spencer on the south coast in the yacht *Enchantress*.

THE ATTEMPTED ASSASSINATION OF HIS EXCELLENCY LI HUNG CHANG.

DR. DEPASSE of Peking sends us the following accurate description of the wound of his Excellency Li Hung Chang:—"On April 23rd, at 4.20 in the afternoon, the Viceroy was wounded. He was in his green chair, and it was his habit to hold his head slightly bent and to look over the top of his spectacles. This detail will aid me in explaining the direction of the wound. The assassin stood on the right of the Viceroy, who was struck beneath the left eye. As soon as possible after the injury I was summoned and arrived. He was stretched upon the sofa, tranquilly smoking his water-pipe as if nothing extraordinary had happened. Presently the medical man, Lin, arrived, and we proceeded together to make a first examination. The weapon used was a revolver of six or seven millimetres calibre, and of American make. The wound of entrance was situated at a point half a centimetre below the inferior border of the orbit on the left side, and about one centimetre outside a vertical line passing through the centre of the pupil. The left lens of the spectacle of the Viceroy was broken by the bullet, the fragments, however, leaving the eye essentially intact. The wound only bled slightly. The left nostril contained clot, and the sputa were blood-stained. Seeing that the assassin crossed over to the right of the Viceroy, and that the latter had been wounded on the left side, one would have expected to find the path of the bullet in an oblique direction; and although the probe which we introduced into the wound penetrated directly from in front backwards to a depth of five centimetres it is possible that at the moment of the accident the Viceroy had his head turned to the right. It is also possible that the projectile had ricocheted on the malar bone, which is very hard. It is possible, too, that the bony fragments concealed the real path of the bullet, and that our probe simply

passed into the maxillary sinus, of which the anterior wall was indubitably fractured. An injection passed in by the wound came out by trickling down the nose. Two suppositions are open to us: either the projectile wounded the anterior wall of the maxillary sinus, crossed this cavity, and buried itself in the posterior wall, or it crossed the maxillary sinus and lodged behind the malar bone in the zygomatic fossa. Of these two alternatives the first was by much the most grave, as it would have given rise to the fear that the presence of a projectile in the cavity of the sinus would put an obstacle in the way of the complete restitution of the elements which go to make up its formation—namely, bone, periosteum, and mucous membrane,—and would bring about a chronic suppurative condition which would be extremely trying for the patient and would lead to an operation such as cutting through the anterior wall of the maxillary sinus to extract the bullet. If we take the second alternative the conditions are very much simplified. There is nothing to stop the perfect and rapid healing of the wound and tissues, and the bullet could stay in the soft parts where it had gone without giving rise to any accident. A little inflammation would be produced, and it would be an easy matter to extract the bullet by a simple incision. It certainly would have been preferable to extract it then and there, but it would be necessary for that to have certain knowledge of the precise point at which it lay, knowledge which we could not acquire without a long investigation. It is obvious, therefore, that this wound, already grave in itself, could take a character still more grave, especially as it was complicated by the presence of a foreign body in its depths. It is easy to preserve perfect asepticity at the point of entrance of the bullet, but the natural opening of the sinus into the nasal fossa holds the door wide open for infection, so it is evident that we must not forget that the healing is not yet completed."

THE DIAGNOSIS OF SMALL-POX: IMPORTANT JUDGMENT.

A CASE is reported from the Dublin Court of Exchequer which may come to have serious consequences for medical practitioners notifying cases of infectious disease under the Infectious Disease (Notification) Act, 1889. A draper of Rathmines brought an action against Dr. John E. Hadden of the same town for damages alleged to have been sustained in consequence of his "having negligently, improperly, and unskillfully diagnosed as small-pox" a disease from which a shop-girl in his employ was suffering. The case was notified as such, was reported to the municipal authorities, and the girl was removed to the hospital. At the hospital the case was diagnosed by Dr. Day, the resident medical officer, as erythema nodosum, the disease being associated with complications. But Dr. Day said the mistake was a very natural one to fall into, and Dr. Hadden, in his evidence, explained that he had given half an hour to the diagnosis, and that there were symptoms which he could only explain as being due to small-pox. In the meantime rumour of small-pox had got about, the plaintiff alleged loss of business as the result of the error, and the jury, after Mr. Justice Murphy's summing up, found a verdict for him, and awarded him £100 damages. On behalf of Dr. Hadden the highest medical witnesses appeared—such as Dr. Little, ex-president of the Royal College of Physicians of Ireland; Dr. Thornley Stoker, President of the Royal College of Surgeons in Ireland; and Dr. J. W. Moore, who had himself been concerned with no less than 3000 cases of small-pox. These all gave evidence to show that the case exhibited symptoms of incipient small-pox, and that Dr. Hadden was justified in the action he took. The Infectious Disease (Notification) Act, 1889, makes it

compulsory on the part of every medical practitioner to notify a case of infectious disease "forthwith on becoming aware that the patient is suffering from" such disease. Dr. Hadden, utilising his best abilities and his utmost care in the matter, did "become aware" of the existence of infectious disease, and experts of eminence say he was at the time right in forming the opinion which he did. There was, therefore, no negligence in the medical sense of the term, and quite apart from the legal question whether such a document as a notification certificate is not privileged where all due care is exercised by a legally qualified practitioner, it becomes a question how far a medical practitioner can be held responsible for action taken under a compulsory clause when no negligence can be proved against him. Vaccination has so modified certain incipient phases of small-pox as to make it difficult in the extreme to speak without risk of error as to every case submitted for our opinion. The report of the Statistical Committee of the Metropolitan Asylums Board for 1893 states that out of 2441 cases sent to their hospitals certified to be small-pox, 81, or 3·3 per cent., turned out not to be suffering from that disease. This shows the enormous difficulty to be contended with, and it indicates how far this legal decision will enable aggrieved persons to proceed against medical practitioners when they have performed their statutory duty to the best of their ability and without a vestige of any negligence. For these reasons we trust that the Dublin case will not be allowed to rest where it is. It is a matter that affects the medical profession as a whole, and it is deserving of serious consideration whether it should not be taken up on their behalf and sent to a court of appeal.

TELEPHONES AND THUNDERSTORMS.

Do overhead telephone wires exercise a controlling influence on the electricity of the atmosphere? That the converse occurs is evidenced only too plainly by the disturbances in telephonic communication which result from the presence or proximity of a thunderstorm. More than one instance may be recalled of a telephone wire being struck by lightning, to the detriment of the instrument and to the discomfiture of the listener. Such a case was commented upon in THE LANCET of May 5th, 1894. But do overhead wires ward off lightning? We are indebted to the *Decorators' Gazette and Plumber and Gasfitters' Review* for the "fact" that the risk to buildings of being struck by lightning in places unprotected by overhead telephone wires is nearly five times greater than in places provided with a telephone system. An immunity of this kind cannot be considered improbable. It is to be remembered that an overhead telephone wire becomes in point of fact a lightning conductor, and in this capacity may act in two ways: (1) by equalising differences of potential it may prevent the occurrence of the disruptive discharge; or (2) receiving a lightning charge it may carry the current to earth. With reference to the first point there can be little doubt that overhead conductors if connected to earth do play an important part in the distribution of atmospheric electricity. Lord Kelvin in a recent paper (read before the Philosophical Society of Glasgow) states that the difference of potential he obtained between the earth and an insulated burning match placed nine feet above the ground was 200 to 4,000 volts. What, then, is the result of permanently connecting by a good conductor the earth and the atmosphere directly above it, a condition which exists in the case of single-wire telephone circuits? Such an arrangement must tend to equalise potential and prevent the accumulation of those charged masses which no doubt form the nucleus of the storm cloud. This equalisation will continue to take place in all conditions of weather. But when a storm does occur it is obvious that if struck by lightning the wire

carries the current to the point of greatest danger—viz, to the instrument and to anyone in its vicinity. Therefore, unless the strictest structural precautions be taken such a wire becomes a source of danger rather than of safety. To obviate this danger every post or support for overhead wires ought to be fitted with a lightning guard, and every instrument, whether using the earth as a return or not, should be fitted with an efficient form of lightning arrester. Where the overhead wires are not connected to earth, as is the case with overhead "lighting mains" and "twin" telephone circuits, any equalising effect upon potential difference is practically lost, and any circuit connected with overhead wires of this kind must be dangerous, inasmuch as such wires become lightning conductors in all but the saving device of an earth connexion. For "lighting mains" it can scarcely be doubted that the underground system is in most respects the better: (1) for obvious reasons connected with the size of the cables; (2) for the electrical reason that if carried overhead no earth connexion is allowable by the rules of the Board of Trade. For telephones the adoption of the "twin wire" system seems to bring with it the advisability of placing the wires below the surface of the ground, inasmuch as this system does away with the earth return as part of the circuit. It therefore appears that from an electrical point of view there may be in overhead wires an element both of safety and of danger. The latter will certainly predominate unless supports be protected with lightning guards and every instrument provided with an efficient "protector"—that is, with an unfailing means of carrying a strong current to earth without passing through the instrument. Is this secured in practice? Can it be secured with any certainty by even the best lightning arrester or earthing device of any description? So long as the coarse expedient of a connecting wire is necessary for the guidance of electrical energy, so long must this question of "wiring," with its safeties and its dangers, be one of great and growing interest. But it may be pointed out that if every house were fitted with an efficient form of lightning guard a greater immunity from lightning discharges would be secured than that which at present exists with the closest network of overhead telephone wires.

LAUNDRIES AND FACTORY ACTS.

It was hardly to be expected that a proposal to bring laundries under the Factory Acts would be carried into effect without some opposition from the industry immediately concerned, more especially so when regard is had to the efforts which were made to include laundries under the Factory Act of 1878, and to the opposition which the proposal encountered. Section 19 of Mr. Asquith's Factory and Workshops Bill enacts that the Factory Acts shall apply to any laundry which is carried on by way of trade or for purposes of gain, and that where steam, water, or other mechanical power is used the laundry is to be regarded as a non-textile factory; in any other case as a workshop. It is, however, enacted that Section 19 shall not apply to any laundry in which the persons employed are members of the same family dwelling there. Section 6 of the Bill provides that if any occupier of a factory or workshop knowingly causes or allows wearing apparel to be made, cleaned, or repaired in any building, any inmate of which is suffering from scarlet fever or small-pox, he shall be liable to a penalty of 20s. The Northern Counties Laundry Association have objected to this section on the grounds that "inmates suffering from scarlet fever or small pox" would only be found where the operatives live on the premises, but that places such as these will be for the most part exempt owing to the saving clause in Section 19. It would certainly seem to us, as we suggested in our leading

article of March 9th last, that there is some ambiguity in the provisions of the Bill in regard to laundries which should be cleared up. Mr. Asquith stated, as we pointed out, that "the Act should apply only to laundries carried on by way of trade, and not the laundries where the persons employed were members of the same family." It is difficult to see how the provisions of the Bill as at present framed will prevent what might be called family laundries from taking in other people's washing, and the Bill should, it seems to us, be amended so as to include all places where washing is taken in for gain. In Section 6 there should too, we think, be an amendment making the prohibition applicable to all dangerous infectious diseases, and not only to scarlet fever and small-pox, as at present; selections of this kind are dangerous precedents. The Laundry Association above referred to also object to Section 13, which proposes to reduce the amount of overtime allowed by the principal Act—i.e., the Factory and Workshops Act, 1878. The association point out that the laundry business is liable to sudden pressure of work, that there is little work at the beginning of the week, and that the work must be done in the week in which it comes in. The association consider that the number of days allowed for overtime by the principal Act should be retained.

AN EPIDEMIC OF PARALYSIS IN CHILDREN.

In the *Medical News* a few months ago Dr. Andrew Macphail of Montreal gave an interesting and exhaustive account of his observations on the cases affected in what was apparently an epidemic of paralysis in children occurring in the State of Vermont. This epidemic commenced late in June, increased during July, and culminated in August, although occasional cases continued to occur during the following few months; by the end of the year the formidable malady had practically disappeared. Dr. Macphail was successful in obtaining notes of 91 cases out of 120 that were affected. In the mode of onset and in the nature of the symptoms the cases varied a little, so that nothing absolutely distinctive can be said as to these points except that there were loss of power, muscular wasting, and the reaction of degeneration in the affected muscles. Occurring as it did in epidemic form it was at first naturally suspected of being epidemic cerebro-spinal meningitis; but in no case were the symptoms typical of this disease present. There was general absence of marked head retraction and of opisthotonos, sensory symptoms were not prominent, the headache was chiefly frontal, and psychical symptoms were neither frequent nor severe. Although indefinite rashes were common, in no case was there any petechial eruption, and the serous membranes were not affected. In only two of the cases were joint symptoms present. Roughly speaking, the clinical condition was characterised by an onset with febrile and digestive symptoms and general malaise, and this was followed by paralysis of one or more limbs which usually persisted, but in some cases passed off, at least to a great degree. In some of the cases there was severe pain in the limbs, in two, as we have already remarked, there was effusion into the joints, while some were unassociated with pain or severe symptoms of any kind. Dr. Macphail also gives notes of six cases occurring in adults, apparently cases of similar character and presumably part of the same epidemic. Unfortunately post-mortem examination was not obtained in any of the fatal cases. Thirteen per cent. of the patients died, but Dr. Macphail, in discussing the probable nature of the affection, comes to the conclusion that it was of the nature of poliomyelitis, with, in certain cases, some inflammation of the peripheral nerves, probably not secondary, but either as an independent affection or as the result of the same cause as in a case described some years ago by Dr. Gowers. In regard to the etiology of the

epidemic Dr. Macphail is inclined to attach much importance to the geological character of the small area in which the epidemic occurred. The Great St. Lawrence and Champlain geological fault culminates in the district, and this fault, with the large number of accompanying smaller ones, must, he thinks, form numerous gaps and reservoirs into which contaminated waters may fall and again burst forth in unexpected quarters. The incidence of the epidemic also in the hot months of the year—a character of ordinary infantile paralysis now recognised for some time—is also noteworthy, and seems to us, taken with the other peculiarities of the epidemic, to confirm Dr. Macphail's opinion that the disease was essentially a poliomyelitis. It has not yet been definitely established that this is a microbic disease, but the occurrence of such an epidemic as this would appear to greatly strengthen such a hypothesis.

THE DEMORALISING TENDENCY OF MEDICAL ADVERTISING.

WE have appealed to the medical practitioners of Southport who are associated with hospitals or sanatoria to assist the profession in the repression of advertising methods by objecting to their name appearing in the newspaper advertisements of their various institutions, and we have every confidence that that appeal will be respected. But we notice in the *Southport Visiter* a writer who is disposed to become the apologist for announcements with regard to local medical men in the local papers. He is not a very violent objector to the ancient methods of the profession which are dictated by modesty and good taste. But he just hints that they are a little out of date and need either explanation or abolition. We hope he will reflect further on the matter and see how one act of advertisement leads to another, and how the attitude of the medical profession with respect to advertisement has served always to maintain clearly the distinction between pretenders and real healers and helpers of mankind.

BACTERIOLOGY IN BUCHAREST.

IN a series of annals published in 1893, but received by us last year, Professor Victor Babes gives an account of the investigations in pathology and bacteriology carried out in the Institute at Bucharest between the years 1889 and 1893. Some of the most interesting papers are those connected with the experiments on glanders, which seems to be a common disease in Roumania. Professor Babes claims to have been the first to describe the glanders bacillus in a paper published at Budapest in the *Orvosi Hetilap*, in which he narrates how he found the organism in the ulcerations and abscesses and in the softening tissues of a man affected with glanders. He gives a series of measurements of the bacillus and also gives the method of culture used; but, most important of all, he points out that the virulence varies considerably in different cases; that certain forms will grow rapidly on agar, blood serum, and even gelatine, whilst others do not grow at all except when the gelatine is kept at a comparatively high temperature. He does not, however, lay sufficient stress upon the fact that the question of variability extends also to the virulence and toxine-forming power of the organism when it is grown outside the body. One of the most important facts demonstrated in recent years is that the mallein-forming power of the glanders bacillus diminishes very rapidly after the organism has been cultivated as a saprophyte even through a few generations. Prof. Babes points out, however, how important it is for cultural purposes first to make cultures on potatoes, as the glanders bacillus grows rapidly enough on this in the first instance; and, secondly, to pass suspected material through a guinea-pig, from which almost pure cultures of the glanders bacillus may be obtained. As regards the method of infection Prof.

Babes is convinced that the glanders bacillus often finds its entrance through the skin, as he has found dilated hair follicles filled with bacilli and surrounded by a zone of embryonic cells, from which zone extends some slight infiltration along the lines of the vessels; whilst in certain patients he has also observed small, reddish, hard papillæ, but without any interruption of the continuity of the skin in the first instance, which gradually develop into ulcers. He has been able to prove this same method of infection by rubbing the glanders bacillus, mixed with lanoline, into the skin of guinea-pigs; and Dr. Nocard has obtained similar results. This, of course, does not take the place of infection by the mucous membranes, which he found to be a frequent point of attack. It is also pointed out that a modified form of glanders is sometimes met with in horses; he speaks of it as pseudo-glanders, and finds that it runs a chronic course, the horse recovering. In Roumania glanders is comparatively common in the human subject, and Prof. Babes describes four cases of this disease in man. The most important point he notes is that as other bacteria are so frequently met with along with the glanders bacillus the real disease is probably very frequently not diagnosed. The conclusions as to the use of mallein (to which Prof. Babes gave the name from its analogy to tuberculin) differ somewhat from those now usually accepted, especially as he maintains that the active product does not ordinarily give rise to any pronounced action at the seat of inoculation in glandered animals, and he appears to rely entirely on the temperature indications in determining whether the reaction obtained was the "glanders reaction" or not. In support of his thesis that glanders is often contracted through the skin, a couple of cases of chronic glanders of cutaneous origin are fully described; one of these cases was fatal, and the other left hospital uncured. The latter patient had never had anything to do with horses; the disease began by cutaneous eruptions without loss of substance; although the eruptions became ulcerated, and around them there was marked phlegmonous infiltration, the processes never became generalised. Associated with the glanders bacillus in this case were many saprophytic organisms, and in cultures it was often some time before the glanders bacillus could be distinguished amongst them. This bacillus did not appear to be specially virulent, as guinea-pigs inoculated with it seemed to recover from the glanders, but to succumb to a saprophytic poisoning at a later stage. In the second fatal case the same general features were observed, and in addition it was noticed that with the glanders bacilli were associated enormous masses of streptococci and saprogenic bacilli—in fact, these far outnumbered the glanders bacilli.

OUR FACIAL TRAITS.

WE are all of us physiognomists. We insensibly read each other's faces and receive favourable or unfavourable impressions which in the main, perhaps, are not bad guides in the conduct of life. We are all, at any rate, influenced by such impressions. Some men there are, no doubt, who, like Talleyrand, "can make their faces wizards to their minds, disguising what they really are"; but Shakespeare makes King Duncan speak too peremptorily when he says—

"There's no art
To find the mind's construction in the face."

Among the papers that have recently appeared which may be read with interest is a suggestive article by Dr. Louis Robinson in *Blackwood* for the present month, under the title of "Trades and Faces." It is in continuation of one by the same author, "On Acquired Facial Expression," that appeared a year ago in the same journal. There have been many attempts from the time of Lavater, and before him, to the present day to place physiognomy on a sound basis,

but it cannot be said that these have been altogether successful or that the observations which have been made have been reduced to any useful or generally recognised system. The nervous mechanism of the face-making forces, by which the repetition of stimuli, acting in constant succession and over considerable periods of time, tend to bring about changes of expression, has been explained on physiological grounds; the influence of environment acting from without through the avenues of the senses, the moral and emotional impulses and "the pale cast of thought" acting from within, have been analysed and studied. We are enabled to trace the causes of facial expression back to muscular action in response to some dominating influence, or to nutritive changes which are induced by disturbances in the sympathetic nervous system, the effects of which become slowly appreciable. We can lay bare, as it were, the physical basis—the plastic organic medium—in which our reason and our passions play their parts on the world's stage of social and intellectual life, giving to each the stamp of his individual identity as well as the certificate, to some extent, of his calling in life. There are streaks of light here and there in the crude mass of facts, and some faint but valuable indications of the why and wherefore of the various aspects we wear. These may one day afford us a clue to the disentanglement of phenomena so apparently complex and enable us to arrange and systematise our knowledge into groups of distinctive casts and expressions of countenances and to construct a scientific system of physiognomy, but at present it is seemingly a far-off science. Dr. Louis Robinson alludes to the influence of the sympathetic nervous system, which is practically independent of the will, on the nutrition and growth of the body, and traces through the aid of its complex functions an explanation of certain curious points of facial resemblances among people whose pursuits and mental habits at first sight appear to put them as far as the poles asunder. He takes the common facial traits seen in certain classes in illustration. Professional musicians, priests, and sensualists, all, as a rule, bear, he says, distinct certificates on their countenances that they belong to the category of those who come under the preponderating influence of the sympathetic system. His paper is provocative of thought and speculation, but the subject forms an interesting rather than a profitable study, for it involves many nice distinctions, and much subtle reasoning about the physics and metaphysics of life.

PROFESSOR TARCHANOFF ON MUSIC AS A THERAPEUTIC AGENT.

PROFESSOR TARCHANOFF of St. Petersburg has been investigating the influence of music upon man and other animals. The subject is by no means a new one. Music was used in treatment by the physicians of Greece and Rome, and the case of David and Saul will naturally suggest itself. In recent times Dagié and Féré have investigated the effect of music upon the respirations, the pulse, and the muscular system in man. Professor Tarchanoff made use of the ergograph of Mosso, and found that if the fingers were completely fatigued, either by voluntary efforts or by electric excitation, to the point of being incapable of making any mark except a straight line on the registering cylinder, music had the power of making the fatigue disappear, and the finger placed in the ergograph again commenced to mark lines of different heights according to the amount of excitation. It was also found that music of a sad and lugubrious character had the opposite effect and could check or entirely inhibit the contractions. Professor Tarchanoff does not profess to give any positive explanation of these facts, but he inclines to the view that "the voluntary muscles, being furnished with excito-motor and depressent fibres, act in rela-

tion to the music similarly to the heart—that is to say, that joyful music resounds along the excito-motor fibres and sad music along the depressent or inhibitory fibres." Experiments on dogs showed that music was capable of increasing the elimination of carbonic acid by 16·7 per cent., and of increasing the consumption of oxygen by 20·1 per cent. It was also found that music increased the functional activity of the skin. Professor Tarchanoff claims as the result of these experiments that music may fairly be regarded as a serious therapeutic agent, and that it exercises a genuine and considerable influence over the functions of the body. Facts of this kind are in no way surprising, and are chiefly of interest as presenting some physiological basis for phenomena that are sufficiently obvious. The influence of the war chant upon the warrior is known to even savage tribes. We are accustomed to regard this influence simply as an ordinary case of psychical stimuli producing physiological effects. Professor Tarchanoff evidently prefers to regard the phenomena as being all upon the same plane—viz., that of physiology,—and until we know the difference between mind and body and the principles of their interaction it is obviously impossible to controvert this view successfully. From the immediately practical point of view we should not ignore the possible value of music in some states of disease. In melancholia and hysteria it is probably capable of being used with benefit, and it is worth bearing in mind in dealing with insomnia. Classical scholars will not forget that the singing of birds was tried as a remedy to overcome the insomnia of Mæcenas. Music is certainly a good antidote to the pernicious habit of introspection and self-analysis, which is often a curse both of the hysterical and of the highly cultured. It would seem obvious to have recourse by preference to music of a lively and cheerful character.

THE DIFFUSION OF SMALL-POX.

IN England and Wales the prevalence of small-pox fortunately happens to be slight, but things are otherwise in both Scotland and Ireland. In London last week there were only half-a-dozen notified cases with a like number of admissions to hospital, against 4, 12, and 8 admissions in the three preceding weeks respectively. The patients in hospital on any Saturday since the first week of April have not numbered 50. During the present month we hear of Lichfield and Derby in the Midlands, and Liverpool in the north-west, having had experience of small-pox, but only to a minor extent. The home counties have been remarkably free during the past month, some small amount being recorded in the vicinity of Romford, though not in that town. In Scotland during the first three months of the present year there were 22 deaths registered from small-pox in the eight great towns, the numbers in the three several months being 8, 6, and 8 respectively, 8 occurring in Glasgow, 13 in Edinburgh, and 1 in Leith; 2 were in vaccinated persons, 3 in unvaccinated individuals, and in as many as 17 no statement is forthcoming with respect to the condition of the deceased as regards vaccination. In April there were 12 other deaths registered in the eight towns, 10 in Glasgow and 2 in Edinburgh; of the deceased, 3 were children under the age of five years, 1 vaccinated and 2 unvaccinated; while 8 others were over the age-period, beginning at twenty years, of whom 4 were vaccinated and the same number unvaccinated. Glasgow is even now suffering from an outbreak, in which the leading feature has been the spread of the infection mainly by the agency of cases concealed or not diagnosed for considerable intervals of time, thus allowing the seeds of the disease to be disseminated far and wide. The wonder is that the prevalence has been kept down to its present dimensions, the total of cases up to the middle of last week being something over 70, with

5 fresh attacks on each of two successive days. The initial case appears to have occurred so far back as early February, in the person of a rag worker, whose attack was directly responsible for 30 cases; another was in a person the nature of whose illness remained undiscovered from the middle of February until the middle of March, giving rise to many attacks; whilst yet another sufferer was taken ill on March 3rd, and the symptoms of small-pox were only recognised on April 10th, persons to the number of 18 having meanwhile caught the infection from him. In still another instance a child was taken by its parents to a dispensary in ignorance of the fact that it was suffering under malignant small-pox, and 6 persons were infected from it. These are but some of the difficulties with which the sanitary officials have had to cope in their endeavours to stay the spread of the disease. Many persons remain under observation in the reception-house. In Dublin the small-pox epidemic wanes very slowly, the number of patients remaining under treatment at the close of the first week of May being, so far as acute cases go, above that of three weeks earlier—namely, 58, with other 30 convalescent patients at Kilmainham South Dublin Small-pox Hospital. The admissions in the same week were 17, or 3 in excess of the previous week, the deaths being 2, each in a person aged between five and twenty years, vaccinated and unvaccinated respectively. There is now reason to fear an extension of the infection to other parts of Ireland. Occurrence of the disease in Enniscorthy, where an outbreak of small-pox has quite recently been notified, is attributed to importation of infection from the capital, and instances in county Wexford are recorded. Wexford town has recently had several cases to isolate, and two cases in Clonmines were removed to hospital at the close of April, the patients being itinerant basket-makers, who had many opportunities for spreading the disease, and on becoming very ill took refuge in a barn, where they were found. The assistance of the Local Government Board inspectors was sought, and Mr. Stafford was on the scene not many hours later. The outlook at present is not altogether satisfactory.

SPURIOUS ANTITOXIC SERUM.

It is a common saying that there are men in this world who would do anything to gain money, but the *miserables* alluded to by the French Minister of the Interior on the 6th of last month in the Chamber of Deputies at Paris must be demons bearing the outward form and semblance of man, and not in reality human beings. In a speech denouncing the infamous traffic which is carried on under the guise of serum therapy, the official who corresponds to our Home Secretary is reported to have spoken to the following effect: "To unhappy mothers whose children have been attacked by croup they sell tubes filled with putrid blood taken in some knacker's yard or elsewhere." Emanating from so authoritative a source this accusation did not, of course, require any confirmation, but had such been necessary it was forthcoming from Dr. Lannelongue, who mentioned several instances in which serious, and even mortal, consequences had attended on the employment of badly prepared serums. Deeply moved by these shocking disclosures, the Chamber forthwith accepted by 516 voices against 2 the first draft of a short law, containing four articles only, which was submitted by the Minister with a view to the extinction of this peculiarly villainous crime. According to the first article, "attenuated viruses, therapeutic serums, modified toxins, and analogous products susceptible of being used in the prophylaxis or the treatment of contagious diseases, as well as substances of organic origin, non-definable chemically, but destined for employment in acute or chronic affec-

tions, by means of subcutaneous injection, shall only be issued, whether gratuitously or on payment, on the express condition that both as regards manufacture and source of origin they have been the object of an authorisation granted by Government after taking the advice of the Consultative Committee of Hygiene and also of the Academy of Medicine." The authorisation is to be temporary and revocable, and a special commission of inspection will be appointed to ensure its efficaciousness. It is much to be hoped that this opportune ordinance will have the effect of nipping the nefarious traffic in the bud. The preparation of therapeutic serums is an operation demanding the utmost delicacy and care. Analysis so far is powerless to determine the purity and curative value of a serum. It is, therefore, manifestly of the utmost importance that everything connected with the production and distribution of so potent a factor for both good and evil should be under the closest control. It must be added, in conclusion, that the serum-protecting *projet de loi* contains a clause to the effect that its prescriptions are not applicable to Jennerian vaccine, human or animal.

"OUR EYES."

A CORRESPONDENT has sent us a circular received by him from the author of a book entitled "Our Eyes," requesting that it may lie on the table of his consulting room, asking that patients may be recommended to him for the glasses they require, and graciously promising, as a reward for such favours, the remission of 15 per cent. of any amount they may pay the optician. We should be blind, indeed, if we did not notice such a circular as one entirely inadmissible. It is marked "private and confidential," and on this occasion we shall treat the question impersonally; but we shall not bind ourselves to do so on future occasions. The very fact that the tradesman who is the author of the circular marks it "private and confidential" is a proof that he is making a proposition to a member of our profession which will not bear publicity, and which is, indeed, uncomplimentary to his sense of honour. The acceptance of such a remission, or rather commission, from tradesmen by medical men has been in principle condemned by judges and by the General Medical Council, and we are amazed that any respectable tradesman's own sense of what is fit should allow him to issue such proposals to the profession.

LEUCOCYTOSIS IN DIPHTHERIA.

A CLINICAL and experimental study of the leucocytosis of diphtheria has been made by Dr. J. L. Morse, who publishes his results in the *Boston Medical and Surgical Journal* for March 7th. He remarks that a great deal of work has been done during the last few years on the subject of leucocytosis, especially in acute diseases. Diphtheria, however, has been rather neglected. As it is an acute disease, with marked constitutional symptoms due to the absorption of the toxic products of bacterial growth, a leucocytosis is to be expected. The observations hitherto reported have shown this to a marked degree. In all the cases that Dr. Morse examined the presence of the Klebs-Löffler bacillus had been previously demonstrated, and none of them were complicated by other diseases, acute or chronic. The blood was in every case taken from the lobe of the ear and examined with a Thoma-Zeiss apparatus. It was diluted (1 to 200) with a 3 per cent. salt solution coloured with methylene blue and the corpuscles in one cubic millimetre were counted. A differential count of from 300 to 500 white corpuscles was then made, the classification recommended by Ehrlich being used; other cover-slips for this purpose were hardened by heat or benzene and stained with Ehrlich's "triple stain." As far as possible the blood was taken at the

same time of the day and between three and four hours after a meal. The condensed results of Dr. Morse's investigations are appended to his paper in the form of a table, arranged according to the day of the disease. It is evident from this table that diphtheria is accompanied by a very marked hyper-leucocytosis, larger even than that found in pneumonia. This has become well marked by the third day, and is probably present earlier. In a general way it increases as the disease progresses, is greatest at the height of the disease, diminishes during convalescence, and disappears with or soon after the membrane. It also roughly corresponds with the amount of membrane, varying with it directly. There are notable exceptions to this rule, however, to be found in the table. In one case where the throat was full of membrane only 8000 white corpuscles were found, whilst in another where the amount of membrane was moderate there were 42,000 white corpuscles. There seems to be no evident connexion between the glandular enlargement and the increase of leucocytes. It is noticeable, however, that the fatal "septic" cases with greatly enlarged glands all showed a very marked hyper-leucocytosis. Some of the mild cases, nevertheless, with little or no enlargement of the glands, showed just as much. The condition of the lungs and kidneys apparently had no influence in determining the number of white cells. It thus becomes evident that the hyper-leucocytosis is not due to any symptom or combination of symptoms, but is the result of some general influence which is present in every case. This influence, Dr. Morse considers, can be no other than that of the toxins absorbed. Whether the individual variation is due to the amount of absorption, to some difference in the virulence of the toxin absorbed, or to some difference in the resistant powers of the persons attacked must, in the present state of our knowledge, be left unanswered.

THE UNCONTROLLABLE VOMITING OF PREGNANCY.

THE last volume of the Transactions of the American Gynaecological Society contains an interesting paper by Dr. Edward P. Davis of Philadelphia on this subject, with a report of three fatal cases. The paper itself and the discussion upon it show clearly the difficulty that often arises in coming to a conclusion whether it is necessary or not to induce abortion. Two of the patients whose cases are recorded by Dr. Davis apparently died undelivered; in the third the uterus was emptied artificially, but the patient died shortly afterwards. There are various local therapeutic measures short of interfering with the pregnancy that appear to have been attended with success. Among these may be mentioned elevating and supporting the uterus, either by means of a pessary or by means of tampons, the application of caustics such as chromic acid to the vaginal portion of the cervix or cervical canal, and scarification of the cervix, though having regard to the weak state of the patient in bad cases the loss of even a small quantity of blood is not a matter of indifference. A measure that must be regarded as more severe, inasmuch as it involves a risk of terminating the pregnancy when such a step has not been deliberately intended, is a moderate dilatation of the cervix. In addition to local treatment, Dr. Palmer Dudley of New York speaks highly of half-grain doses of cocaine and three-grain doses of monobromate of camphor internally. It must be remembered that even the induction of abortion will not necessarily save the patient if interference is too long deferred. Among symptoms that should suggest the necessity of emptying the uterus are especially the presence of coffee-ground material in the vomit, substernal pain and distress, with marked anæmia and emaciation. Yet every obstetrician of experience knows how unaccountably, even when the patient seems in a bad way, sudden improvement may set in, the vomiting ceasing

and normal delivery taking place at term. When the symptoms that have been mentioned are well marked it is better, however, to occasionally interfere unnecessarily rather than take the risk of deferring interference till too late. A therapeutic measure of some clinical value is to impress on the patient that the induction of abortion will be necessary if the vomiting does not cease or diminish by a certain time—three days, for instance. In some such cases, and especially if the patient objects to the operation, an immediate improvement may be observed.

LIBELLING A PROFESSION.

IN a paragraph signed "Dodo," taken from *Reynolds's Newspaper* of May 5th, the author says he never thought the medical profession too scrupulous in its methods. He goes on to say with the air of an irresponsible but infallible critic: "The experimental operations conducted by medical students and their teachers in the public hospitals put their misbehaviour beyond doubt. It is astonishing the cynical frankness with which they avow their malpractices. Thus, on the question of the putting to death of patients who are incurable sufferers, as to which something may be said in its favour, we sometimes find doctors conspiring with the relatives to accomplish this end, without asking the consent of the patient. When a doctor does this we think the medical murderer is going a little too far." Such critics take refuge in generalities. Perhaps the dignified course for the profession is to take no notice of such cheap abuse of men who do more to relieve suffering in a day than such scribblers do in a year. The putting to death of incurable sufferers is not the sin of our hospitals. Their responsibility is just the other way, and no candid and generous observer of their work can fail to see the enormous scale on which they prolong and brighten lives otherwise condemned to hopeless and depressing suffering. We challenge our contemporary to dare to insert the libel directed so glibly against a whole profession against any one of its members in particular.

THE INDIAN CANTONMENTS ACT.

ACCORDING to the intelligence from India published in the *Times* of the 10th inst., it is satisfactory to find that the new army reorganisation scheme is reported to be working so far very satisfactorily considering the many details which had to be settled and the numerous changes which it involved; but it is very far from satisfactory to find that the only contagious or infectious diseases mentioned in the new rules under the Indian Cantonments Act are cholera, small-pox, diphtheria, and typhoid fever. Persons suffering from any of these, and refusing to go to or remain in hospital, are liable to removal from the cantonment, but those suffering from that contagious disease which works such havoc among soldiers are not interfered with; they are, it seems, to be allowed every facility for spreading a special form of contagion among our troops with perfect impunity. Can anything be more monstrously absurd and opposed to common sense? A woman may be notoriously suffering from disease and either does not seek treatment or refuses to be treated in any of the institutions specially provided for the purpose; she is to be permitted to pursue a calling which, in that condition, is a highly dangerous one, and there is to be no power vested in anyone to stop her. It is permissible, under the present ruling, to warn the subjects of such infectious diseases as are of relatively rare occurrence that they must either go to hospital and be treated there, or quit the cantonment; but such power is altogether withheld from the cantonment authorities in the case of those who are alleged to be the source and origin of another particularly common and highly contagious disease. Surely there is no unwarrantable interference with the liberty of the subject here unless it is an unwarrantable

interference to prohibit such persons from doing grave injury to other people. It seems to us to be quite as justifiable and logical to require that, under the circumstances, they should place themselves under treatment, and peremptorily be ordered to leave the cantonment if they refuse to do so, as to prohibit people from smoking or using lucifer matches in the vicinity of powder magazines. They are in both cases alike sources of danger to the community against whom it is necessary in the public interest to take such precautions and safeguards as are obviously indicated.

THE LATE MR. DURHAM.

A LARGE congregation attended at St. George's Church, Hanover-square, on Friday, May 10th, upon the occasion of the funeral of Mr. Durham. Among those present were Sir Richard Quain (President of the General Medical Council), Mr. Christopher Heath (President of the Royal College of Surgeons of England), Mr. Reginald Harrison and Mr. Willett (Vice-Presidents), Sir William Broadbent, Sir William MacCormac, Mr. Lushington (treasurer of Gay's Hospital), Mr. Howse (senior surgeon to Gay's Hospital), Dr. Braxton Hicks, Dr. Pye-Smith, Sir William Dalby (President of the Medical Society of London), Dr. Wilks, Mr. Trimmer (secretary of the Royal College of Surgeons of England), Dr. Holman, Mr. Joseph White, Dr. Pavy, Dr. Goodhart, and Dr. Langdon-Down. The theatrical profession was represented by Mr. Henry Irving, Mr. S. B. Bancroft, and Mr. Cooper Key who attended on behalf of Mr. J. L. Toole. The mourners were Mr. Herbert Durham and Mr. Frank Durham, the two surviving sons, and Mr. Frederic Durham and Mr. Francis Durham, the brothers of the deceased. The Rev. David Anderson officiated, and at the conclusion of the service the body was removed to the London Necropolis Company's station, Westminster Bridge-road, and conveyed to Woking, where it was cremated, the ashes being placed in an urn and deposited in a niche at the crematorium.

FRIEDREICH'S ATAXY AND IDIOCY.

In the last number of the *Dublin Medical Journal* Dr. Nolan gives an account of three cases of Friedreich's ataxy, all occurring in the same family, and associated with well-marked mental deficiency. The father of the patients (now aged forty-nine) has been a habitual drunkard from an early age, but with the exception of gastric and hepatic ailments, the results of his drinking habits, has enjoyed good health and has never suffered from syphilis. Nor is there any neurotic history in his father or mother. The mother of the patients is a hardy and healthy woman and has borne eight children. Of these, two died from scarlet fever and three—the third, the fifth, and the eighth—are the subjects of Friedreich's ataxy with mental deficiency; the others are described as healthy and intelligent. The eldest patient is a girl aged twenty-two, 4 ft. 7 in. in height, and weighing 7 st. She is stunted and has a lateral curvature; her features are said to be of the Malayan idiotic type, and in animation are expressive of good humour. There are slight strabismus and distinct nystagmus, but the pupillary reflexes are normal. The patient has marked lack of control over tongue and lip movements, and her articulation is indistinct and slovenly. She has evident uniform enlargement of the thyroid gland; the breasts and external genitalia are immature. There is ataxy in the hands and also great unsteadiness in walking, and the knee-jerks are absent. The sphincters are unaffected. The second patient is a lad aged fifteen, whose appearance and expression are similar to those of his sister. His motor symptoms and his articulation also are similar, and his thyroid gland is enlarged. The knee-jerk, however, is present and exaggerated. Both these patients are inmates of an asylum, having been admitted as "dangerous idiots" on account of assaults which they were said to have

committed. The third patient, a boy aged ten, is still at home. His expression is identical with those of his brother and sister, and his symptoms are similar. The thyroid gland, however, seems to be of normal appearance and size. The ataxy is advanced and speech is very rudimentary. The knee-jerks are absent and his psychical condition is much impaired. These cases form a very interesting group, and seem to show that the presence of the knee-jerk in a case otherwise identical with Friedreich's disease must not be regarded as of undue importance. In two of these cases it was absent; in one it was present, although in other respects the cases were almost identical. The absence of deformity of the feet in all the cases is also interesting, but, as Dr. Nolan points out, it is quite a mistake to regard this deformity of "humped foot" or pes cavus as pathognomonic of Friedreich's ataxy. The association of imbecility is also of great importance, and when we remember that, according to current views, Friedreich's ataxy is a developmental neurosis, it is really strange that psychical symptoms are not present oftener than they seem to be.

A MEDICAL MAN'S SERVICES TO A DYING FELLOW-PASSENGER.

A PARAGRAPH is going the round of the papers reporting an action by Mr. Fox of Clapham-road for services rendered to Mr. Lewis, a passenger seized with hæmatemesis on board the steamship *Nyptune*, in a summer trip to Norway, with no official surgeon to look after the passengers, which numbered 100. Mr. Fox's claim was twenty-five guineas for an attendance of thirty-six hours. The patient was landed at Newcastle, and died in the infirmary there. The judge said the plaintiff was entitled to his ordinary charges, and gave him £9 3s. and costs, including £5 paid into court. We are informed—and it is obvious from the published facts—that the case was one of great anxiety, requiring the frequent attention of Mr. Fox. The exact sum he charged may be a matter for difference of opinion, and can scarcely be judged by those who are not acquainted with all the facts. But it would be monstrous to maintain that he was not entitled to be paid for his professional services. We have his authority for saying that he would have settled the claim for £10 before it came into court. Obviously such steamers should carry a medical man as part of their equipment. It is hard, indeed, that a medical practitioner on his summer holiday should be expected to attend grave cases of disease without remuneration. *En passant*, we believe that a ship carrying passengers numbering 100 and upwards must carry a surgeon.

THE CONDITION OF THE NEWTON ABBOT WORKHOUSE.

THE Newton Abbot guardians were apparently in need of a stimulus in the matter of their very defective workhouse, and we are glad to see they have received one at the hands of their medical officer. Dr. Culross, in presenting his last quarterly report, reminded the guardians that as long as the present condition of affairs continued he was only able to recapitulate existing defects, all of which were dependent on structural cause. These defects, Dr. Culross observed, entailed not simply inconvenience, but actual suffering and possible danger. The officers were unable to perform their duties and were exposed to blame for shortcomings which were beyond their control. Among the defects specified by Dr. Culross we note the absence of isolation wards, receiving wards unfit for their purpose, unsuitable sick wards, vagrant wards "utterly bad," insufficient hot water and bathing accommodation, an inadequate laundry, and no suitable recreation ground for women. As regards the existing receiving wards, Dr. Culross reported that the men's was occupied by a case of erysipelas, and the women's by a man

suffering from scabies; a third case of contagious disease was isolated in the sewing-room. Considerable discussion and some confusion followed, we are told, the reading out of this somewhat appalling category, and Mr. Ley, one of the guardians, remarked that Dr. Culross would have failed in his duty had he not presented the report; week after week these matters had been talked of, but nothing had been done. Although it appears that some attempts were made at the meeting to still further postpone matters we are glad to see that the guardians decided to forward forthwith to the Local Government Board the amended plans of the buildings, which will, we trust, put an end to the necessity of such reports as Dr. Culross has considered it his duty to make.

THE COLONIAL MEDICAL COUNCIL.

THE report of this Council for the year 1894 tends to show that the Council is alive to the growing importance of preserving the standard of professional qualifications in South Africa. It has been resolved to maintain the regulations admitting as registrable only those degrees covering a minimum curriculum of, respectively, four and three degrees for medical men and dentists. Five prosecutions have taken place, on the initiative of the Council, against unlicensed persons reported to be practising as medical men or dentists. Four have resulted in conviction, and in the fifth the accused person is committed for trial. Testimony is borne by the Council to the readiness with which magistrates and other officials assist in investigating charges of this sort. It is very gratifying to be assured of this. In a colony so open to adventurers of all kinds it is serious to think what might happen if care were not exercised in guarding the portals of the profession. Charges of disgraceful conduct have been dealt with in two cases. In one case a name was restored to the Register. In the other charges were made by the manager of an insurance office against a medical man for certifying for an insurance in the case of an applicant who shortly afterwards died; the facts were anxiously investigated, with the result of finding the accused guilty of disgraceful conduct. Thereupon His Excellency the Governor, in the exercise of his discretion, withdrew the licence of the practitioner.

It was a matter of comment by many of those who were present at the University of London on Wednesday that, by an oversight on the part of the Lord Chancellor, no mention was made of the loss the University had sustained by the death of two such distinguished graduates and eminent Fellows as the late Sir William Savory and the late Sir George Buchanan.

At a Council held at Windsor on Saturday, May 11th, Dr. Richard Thorne Thorne, C.B., F.R.S., medical officer to the Local Government Board, was nominated by Her Majesty a member (for England) of the General Council of Medical Education and Registration for a period of five years, in succession to Sir John Simon, K.C.B., F.R.C.S., resigned.

THE annual dinner of the old students of King's College, London, will be held at the Holborn Restaurant on Monday, June 24th, when the Right Rev. the Lord Bishop of London, D.D., will occupy the chair.

THE Society of Obstetrics and Gynecology of Bordeaux, in organising a Congress for Aug. 8th on the occasion of the Exposition, has elected Dr. Robert Barnes "Président d'Honneur."

WE have great pleasure in stating that the condition of Professor Huxley's health is much improved; the cough and

expectoration have almost ceased, the temperature is normal, and the appetite returning. He sleeps well, and the weakness is less marked.

THE ROYAL MEDICAL BENEVOLENT COLLEGE DINNER.

SOME 240 guests assembled in the prettily-decorated East Foyer dining-room of the Imperial Institute on Wednesday last to take part in the twenty-seventh festival of the Royal Medical Benevolent College. The Right Hon. A. J. Balfour, M.P., presided, and there were present, amongst others, Sir Richard Webster, Q.C., M.P., Mr. Christopher Heath (President of the Royal College of Surgeons), Sir John Williams, Sir Dyce Duckworth, Sir W. H. Broadbent, Sir W. Roberts, Dr. E. Long Fox, Dr. Michael Foster, Dr. Constantine Holman, and Mr. Wakley.

After the loyal toasts had been duly honoured Sir RICHARD WEBSTER, in an amusing and witty speech, proposed "The Medical Corporations," which was responded to by Mr. Christopher Heath, Sir Dyce Duckworth, and Dr. E. Long Fox.

The CHAIRMAN, 'in rising to propose "Success to the Royal Medical Benevolent College," said: "It is not necessary probably that I should describe to an assembly like this the characteristics of the great charitable institution in whose cause and in whose behalf we have met here to-night. It will suffice if I briefly remind you that it is intended to carry out the double function of giving pensions to those members of the profession or their widows who most deserve them and of supplying the best possible education to their children. That such an institution is useful—nay, that it is necessary—I imagine few will be disposed to deny, and that the great medical body of the United Kingdom, numbering not less than 32,000 persons, should have an institution like this to serve the needs of their less fortunate members is what we should have all expected. Gentlemen, I am speaking not as a member of the medical profession, but as a member of the general public; and appealing to that general public to assist in this work the question arises, naturally and necessarily, why this great body of 32,000 persons should look outside their own limits in order to obtain assistance for a charitable institution whose beneficent efforts are necessarily confined to their own number. I think the answer to this question is an easy one, and is to be found in the obligations which the outside public, in whose name I venture to speak to-night, are under, and the benefits which they have derived from that great profession to whom the majority of you belong. Is it not true, am I not justified in saying, even in your presence, that there is no body of men, select them how you will or where you will, who have given to that public to which we now appeal a larger measure of gratuitous service? In every district, in every parish, almost in every street, you will find that the medical profession have ever been ready to go—with or without remuneration—to the succour of the unfortunate, and that they have lavished the treasures of their time and skill on those who from worldly circumstances were but very ill able to repay them. And this should call to our mind the fact that the great charity on whose behalf I speak is not called into existence merely to subserve the interests of the incompetent or unsuccessful members of your profession, but, on the contrary, there is many and many a case of a medical man who, from no want of skill, certainly from no want of energy, zeal or public spirit, has carried out his great work in districts and under circumstances which made him indeed not less—but it may be more—useful to mankind, but made it almost impossible for him to leave an adequate provision for his wife or for his children. I think that these members of the profession, not the waifs and strays, not the wastage which must necessarily occur, but men constituting very often eminent members of the body in point of zeal and devotion—these are the people that this charity subserve. The general public are bound to feel that among the great charities calling for support this does not rank among the least. I cannot forget that the great debt which humanity owes in the past to the healing art is increasing, and seems likely to increase in a greater and greater ratio. The application of science to all the arts, the successful application of scientific method and knowledge to all

the arts, is one of the most remarkable characteristics of this and the last generation, but I do not know that this shows itself more prominently than in the province of medicine where science and art are every day joining hands more and more closely. Every day it is becoming more and more the work of the scientific expert. I do not know if we are over-sanguine in anticipating a period when we shall not only have an incomparable insight into the nature and cause of disease, but shall be able to command in greater measure the remedies which may be successfully applied. A friend of mine with whom I was discussing these happy prospects told me that he did not see any valid or sufficient reason why, when medicine was sufficiently understood, and those temperate habits which medicine may counsel, but which it cannot enforce, obtain a deeper hold on the public, as undoubtedly they will, the span of human life may be extended to the patriarchal term of 120 years. I do not know whether that forecast is over-sanguine, but it suggested to my mind a reflection which has frequently occurred to me before, which is that death is not the enemy the medical profession have to fight against; it is rather pain, and that disease which renders us ineffectual for practical work. I often hear of cases in which I am told that by the extraordinary skill of some great practitioner and by the appliance of all the most recent medical discoveries, it has been found possible to prolong for some few days or weeks longer a doomed life. Those are among the performances of your science; they are not, I think, among its triumphs; and for my own part, I think if medicine can ease us of our pain, if it can render that span of life allotted to us more available for practical work, more efficient for doing the duty cast upon us, more useful for developing the activities with which we have been endowed, we may relieve it of the duty of prolonging a painful and useless life—a life, it may be, painful to the possessor, a life which may be useless and worse than useless to those who wait around the sick bed. After all, if death be our enemy, death is sure to conquer; but it may be—indeed, it has been—within the resources of your art to relieve from suffering, in itself an evil which only those who have gone through it can properly estimate, and restore to active life many who would otherwise linger year after year, a burden to themselves, and, what must even weigh more upon them, a burden to all those whom they love best. In conclusion, I would not merely appeal to the members of the profession, but to the outside public to support the greatest medical charity which now exists in England, and to make an appeal to them not to allow this charity to lose any of the great usefulness which it now exercises by the lack of public support. I couple with the toast the names of the treasurer and headmaster, Dr. Holman and the Rev. Hart Smith, and everyone knows how much the success of an institution like this depends upon the men who carry out the work.

Dr. HOLMAN, in responding, referred to the great and useful work of the College. He alluded to the medical Press, who had greatly helped him to extend the charity to the pensioners. He also mentioned the names of Mr. Burdett, Dr. Dawson Williams, and Mr. Wakley; the last-named gentleman had not only supported him, but on behalf of the Proprietors of THE LANCET in 1892 handed him a cheque for £1000 for the purpose of extending the charity. It was his strong desire to leave to the younger generation who would succeed in the management of the College a legacy founded upon a firm financial basis of absolute security.

The Rev. T. N. HART SMITH also responded.

Dr. JOHN LUMSDEN PROBERT proposed the toast of "The Chairman," which was acknowledged by Mr. Balfour; and the "Hon. Local Secretaries" being proposed by Mr. Henry Morris, and responded to by Mr. Edmund H. Galton, the festivities came to a close.

Subscriptions amounting to nearly £1700 were announced, including 100 guineas from the Messrs. Wakley, 25 guineas from the Right Hon. A. J. Balfour, 21 guineas from Sir Richard Webster, 10 guineas from Sir J. Russell Reynolds, and 10 guineas from Mr. Christopher Heath.

NEUROLOGICAL SOCIETY OF LONDON.—A clinical meeting of the society will be held at 20, Hanover-square, on Thursday, June 6th, at 8.30 P.M. Members wishing to show cases are requested to communicate with the secretaries not later than May 25th. This meeting will be a special one for the election of a vice-president in the place of the late Dr. Hack Tuke. (The council nominate Dr. Geo. H. Savage.)

REPORT OF THE COMMITTEE ON PRISONS.

II.¹

COMING next to the "Treatment of Prisoners" the committee deal first with the question of accommodation, as to which they say that serious charges of overcrowding in the London prisons have been made. The Prisons Act of 1865 provides (Section 17) that "in every prison separate cells shall be provided equal in number to the average of the greatest number of prisoners, not being convicts under sentence of penal servitude, who have been confined in such prisons at the same time during each preceding five years." Further, the same Act, Schedule I., Regulation 26, provides that: "Every male prisoner shall sleep in a cell by himself, or under special circumstances in a separate bed placed in a cell containing not fewer than two other male prisoners, and sufficient bedclothes shall be provided for every prisoner. A convicted criminal prisoner may be required to sleep on a plank bed without a mattress during such time as may be determined by the rules of the prison. Epileptic prisoners or prisoners labouring under diseases requiring assistance or supervision in the night may at any time, notwithstanding this regulation, be placed by order of the surgeon with not fewer than two other male prisoners." The committee find that the law, as laid down in Section 17 (1), has been observed, and the required number of separate cells has been provided. But, owing partly to the growing practice of sending convicts to local prisons and partly to the occasional arrival of unusually large drafts of prisoners, Regulation 26 of Schedule 1 has not been adhered to. Ordinary prisoners have been placed in association, and although this may have been only for a single night the committee are clearly of opinion that the margin of accommodation ought to be sufficiently ample to make these occurrences impossible. Prison officials without exception agreed that such association is most objectionable morally and physically, and the committee think that, with a view to its avoidance, the Prison Commissioners ought to have larger powers than they possess in the way of sanctioning or refusing transfers on their own responsibility. The committee hold that for the purposes of Section 17 (1) of the Prison Act, 1865, all classes of prisoners should be included in calculating the average of the greatest number of prisoners in each of the preceding five years. In this we quite agree, and, indeed, the wording of the section appears to be cumbersome and to have opened a door to evasion of the spirit and intention of the Act itself. With regard to association under Regulation 26 there is, the committee say, some difference of opinion; but all witnesses agree that where association is ordered on medical grounds it is essential that adequate supervision should be secured. The committee think that association in sleeping cells should not be allowed under any circumstances, except for medical reasons, and upon the express recommendation of the medical officer.

On the subject of "Visits and Communications" some experienced officials state that the present rules are quite adequate and need no alteration, while many witnesses were in favour of extending existing privileges. The general impression appears to coincide with Sir Edmund Du Cane's view that it might be advisable to allow more frequent letters and visits after three months on the condition that the increase of privileges should be in accordance with the mark or stage system. If it should be in any sense an invidious task to give discretionary powers to the Governor, it is suggested that the Visiting Committee should have power to consider each individual case on its merits. For ourselves we question the advisability of relieving the Governor of this responsibility or privilege, whichever light it may be taken in; for if he is the proper man for the post he ought to be the best able to decide as to the value of relaxing the rules in particular instances. The multiplication of opportunities for appealing by prisoners past the authority of the Governor has a tendency to weaken his authority, and the Visiting Committee must be guided by what the Governor says in the matter. To our thinking the judicious relaxation of rule so as to promote wholesome communication with desirable relatives and friends on the part of a prisoner is greatly to be commended so long as care is taken to avoid any

¹ Part I. was published in THE LANCET of May 4th, 1895.

"weakening of the penal machinery" thereby. As the committee in their summing up on this point say: "No hard-and-fast rules at any period should be allowed to keep from a prisoner any good influence which might help to reclaim him or save him from becoming a permanent member of the criminal classes." No doubt this is rather a utopian statement of the case and not likely to be carried out in practice for many a long day; but in principle it is both sound and sensible.

On the subject of "Prison Offences" the committee are of opinion that, speaking generally, the present regulations governing punishments for prison offences have worked as well as could have been expected. Whatever may be said or proved against the nature or amount of the punishment, the broad fact remains that the great majority of prisoners serve their time without any punishment at all. The following figures given in the report are interesting; they are for the year ending March 31st, 1894:—

	Numbers punished.	Not punished.	Total number.
Convict Prisons	2,068	3,389	5,487
Local Prisons	23,071	134,831	207,702

Of the 306 convicts discharged from Portland Prison as many as 135 earned their full remission, and 125 were released within three months after the minimum period of their sentence had expired. It is a pity that the committee, having gone so far, did not go one step further and give us an analysis of the kind of offences for which this number of punishments was meted out. As an indication of vicious disposition there is all the difference in the world between talking in chapel and at other forbidden times or non-completion of task on the one hand, and insubordination, destructiveness, or personal violence on the other. The committee say that some competent witnesses attribute a number of offences to the nature of prison life, a statement as to which we think there can be no sort of doubt; for where discipline or even disciplinary routine is supposed to prevail there is at once created a possible class of offence which does not rise into prominence in ordinary social conditions. "It is impossible to conceive any system of prison discipline adequately coercive which should reduce or lead to absolute submissiveness a class of men whose previous lives have conclusively shown that when not under restraint they are unable to observe the laws and regulations of social life. Bearing this in mind, and given the fact that prison life necessarily means continuous and severe discipline, it is evident that the number of prisoners who receive no punishment during their service is a remarkable tribute both to the character of the discipline maintained and to the tact and forbearance of the prison staff." The evidence has led the committee to the belief that during recent years there has been a distinct move forward in the direction of mitigating the severity of prison punishments. The use of the entirely dark cell has been discontinued since the publication of the Report of the Royal Commission on Irish Prisons in 1884. Corporal punishment has decreased in a striking degree in local prisons, but the percentage in convict prisons remains about stationary. Standing Order No. 94 of the Commissioners states that, as the result of experience, "discipline is not better maintained by resorting commonly to severe punishment, which should be reserved for use when milder means have been tried unsuccessfully and when it is necessary to apply them on particular occasions." The committee say that this opinion (of the Commissioners) carries much weight, and it strengthens their belief that the main fault of our prison system is that it treats prisoners too much as irreclaimable criminals instead of as reclaimable men and women. Under the present rules, while a Governor cannot inflict more than three days' bread and water diet in succession, after which must come an interval of twenty-four hours, the Visiting Committee can for a single offence sentence a prisoner to fourteen days in a punishment cell, with No. 1 bread and water diet, alternating every three days with No. 2 and No. 3 diets. The committee think that according to the intention of the Act of 1877 a prisoner should only be committed to a punishment cell on penal diet for fourteen days; and an interval of at least three days should elapse before any additional period is imposed in respect of a fresh offence, or an offence distinct from that for which the punishment was inflicted, and this second period should only be inflicted with

the sanction of the medical officer. The committee have made special inquiries as to whether offences are committed in consequence of the petty tyranny or harshness of warders. It is only in human nature, they say, that there should be instances of unfair and unwise treatment of prisoners by warders in their constant daily personal relations with them; but, they add, it is only a matter of justice to them to say that, so far as the committee have been able to find out, as a body they discharge their most difficult and responsible duties with forbearance and kindness.

With reference to "Prison Labour" the committee have felt it to be necessary to go at length into this branch of the subject, both because of its great intrinsic importance and because in previous inquiries it has been passed over with but little notice. It resolves itself into two main parts—(1) unproductive labour, cellular or associated, and (2) productive labour, cellular or associated. As regards convict prisons in the first instance, the committee have no recommendations to make. Convicts for the first nine months of their sentence are kept in isolated confinement. For the first month they are kept at first-class hard labour, and are subsequently engaged at oakum-picking, mat-making, tailoring, or any suitable work which it is found possible to give them. After nine months all convict prisoners, unless physically disabled or found specially qualified for other work, are put to associated labour in public works, quarrying, farming, land reclaiming, and so forth.

Coming next to local prisons and dealing with unproductive labour, the committee in consideration of this question "start from the principle that prison treatment should have as its primary and concurrent objects, deterrence and reformation." It follows, therefore, that it is desirable to provide labour which, in conjunction with the general prison discipline, does not impair the one and which does "include the other. Applying this general conclusion it necessarily follows that unproductive labour, including all purely mechanical work on cranks or treadwheels, and in the case of women oakum-picking, except as a punishment, should be entirely abolished wherever possible."

First-class hard labour involves a mechanical and unvarying exertion for six hours a day for a month. All classes of witnesses agreed that as an occupation labour which is unproductive, or apparently so, is most undesirable. Sir Edmund Du Cane speaks in strong terms of the "punishment of hard, dull, useless, uninteresting, monotonous labour. It is necessary to resort to this for its penal effect. There is, nevertheless, a limit to the time during which a prisoner can be advantageously subjected to it, for it is decidedly brutalising in its effect. To men of any intelligence it is irritating, depressing, and debasing to the mental faculties; to those already of a low type of intelligence it is too conformable to the state of mind out of which it is most desirable that they should be raised." The strongest argument against this kind of labour is, in the opinion of the committee, the fact that it keeps the prisoners in a state of mental vacuity. The class of labour being on all hands unhesitatingly condemned as undesirable and mischievous in its results, the question always comes to be, What can be substituted for it? To this no satisfactory answer has yet been forthcoming, one chief difficulty lying in the fact that the large local prisons are mostly situated in the heart of large towns and the labour has to be found within the prison walls. The committee suggest the possibility of making arrangements for sending the hard-labour men to prisons specially chosen in the country, where they could be set to work on the land or at reclamation. This would be a costly plan, but in our opinion it is well worth full and serious consideration. If it could be shown to be likely to result in a clear gain in the matter of strengthening and adjusting personal character in those who have a bias for vicious and criminal ways, the question of cost ought not to outweigh considerations pointing to an ultimate and great social reform of the truest type.

"Productive Labour" is necessarily dealt with under the two heads of cellular and associated, with regard to the respective merits of which there appears to be much difference of opinion. On the one side it is maintained that better discipline and a better moral tone are secured by keeping prisoners in isolation; and on the other that associated work is a more natural state, that it is more interesting, and helps to keep the prisoners from morbid depression. The committee do not agree with the view that separate confinement is desirable on the ground that it enables the prisoner to meditate on his misdeeds; but they are disposed to agree

that the separate system as a general principle is the right policy, resting as it does on two considerations—viz., that it is deterrent and that it is a necessary safeguard against contamination; but the committee are not of opinion that association for industrial labour under proper conditions is productive of harm—on the contrary, they believe the advantages largely outweigh the disadvantages. They point out that this limited form of association is desirable for many reasons, having reference especially to the relief from dull monotony of life, privilege afforded for good behaviour, possibility of teaching trades, and to greater healthfulness. To our mind it possesses also the advantage of tending to encourage the development of a more natural and more stable frame of mind; while at the same time there is afforded a test or criterion of the individual's trustworthiness or his improved capacity for behaving himself amongst others when he is restored in due course to normal social surroundings. In conclusion, the committee state that "they have no hesitation in recommending that the practice of association for industrial work should with due caution be extended gradually throughout the prisons. Satisfactory results must largely depend on the discretion of the prison authorities in making selections of prisoners for associated work; and in any case they would be materially assisted by a careful classification," such as the committee later proceed to recommend.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on the 4th inst., the President, Mr. Christopher Heath, being in the chair.

Mr. H. J. Waring, F.R.C.S., was introduced, and the President handed him a cheque for the amount of one year's dividends from the Jacksonian Fund, as Jacksonian Prize for the past year, together with the instrument declaratory of the award thereof.

The Committee of Management of the Examining Board in England presented a report, dated April 22nd, in which they had revised their report dated March 4th. The committee had been requested by the Royal College of Physicians of London to further consider their report in order that they might instruct the Colleges in fuller detail than they had already done as to what should be said in reply to the criticisms of the inspector of examinations touching the examination for the diploma in Public Health granted by the Colleges. The further report is as follows:—

"The committee have held a conference with the Examiners in Public Health, and find that at the last examination, which was subsequent to that visited by the inspector, all the candidates in Part I. were efficiently tested in Practical Bacteriology, the examiners understanding that such examination came within their province under the existing schedule.

"As a result of the conference, and having had the valuable advice of Dr. Thorne Thorne, Dr. Stevenson, and Professor Notter, the committee recommended that the syllabus of the examination for Part I. be printed as follows, and that every candidate be required to undergo this practical examination:—

"1. Physics in their application to health, with reference to (a) warming and ventilation; (b) water-supply, sewerage, and drainage; (c) sanitary construction. 2. Meteorology in relation to health. 3. Chemistry, with special reference to food, air, soil, and water. 4. Microscopical examinations, as applied to air, food, and water. 5. Bacteriology, including the cultivation and recognition of micro-organisms. 6. Geology and soil in relation to drainage and water-supply.

"With respect to the examination in infectious diseases, the committee, having discussed the question with the examiners, adhere to their report on that subject."

The report was approved, and a further report from the same committee was also approved. It was as follows:—

"The Committee of Management beg to make the following recommendations. 1. That on the application of the Dean of the Westminster Hospital Medical School the course of Clinical Demonstrations in Lunacy given by Dr. Mercier at the London County Asylum, Cane-hill, be recognised so long as he shall hold the lectureship on Mental Diseases in that

medical school. 2. That the following institutions be added to the list of recognised places of instruction in chemistry, physics, and practical chemistry: (a) the Grammar School, Bromyard; (b) the Nonconformist Grammar School, Blahops Stortford. 3. That the Hospital for Sick Children, Great Ormond-street, be recognised as a place of study during the fifth year of the curriculum."

The President reported that, in pursuance of the provisions of the Bradshaw Bequest he had chosen Mr. N. C. Macnamara as the Bradshaw Lecturer for the ensuing collegiate year.

The President, the Vice-Presidents, Mr. Bryant, and Sir William MacCormac were appointed the members of a committee to superintend the arrangements for the conversations to be held on Aug. 2nd on the occasion of the meeting in London of the British Medical Association.

It was resolved that the annual meeting of Fellows of the College for the election of members of the Council shall be held at the College on Thursday, July 4th next, at 1.30 P.M.

It was resolved that, in pursuance of Section XXIII. of the Regulations of the Council, a meeting of Fellows of the College shall be held at the College on Thursday, July 4th next, at 5 P.M. The Council will determine what subjects, if any, shall be referred to the consideration of the meeting.

A letter dated April 7th was read from Mr. E. Almack, Secretary of the National Dental Hospital, communicating the following resolution—viz.: "That the Medical Committee of the National Dental Hospital and College request the licensing bodies to arrange for an examination in mechanical dentistry for dental students previous to their commencing their surgical training." The matter was referred to the Board of Examiners in Dental Surgery to consider and report.

A committee consisting of the President, the Vice-Presidents, Mr. Hutchinson, and Mr. Bryant was appointed to consider and report to the Council on the Midwives Registration Bill.

THE UNIVERSITY OF LONDON.

LONDON UNIVERSITY COMMISSION BILL.

THE following is the text of the Bill intituled an Act to make further provision with respect to the University of London, introduced by Lord Playfair in the House of Lords on May 9th:—

Whereas the Commissioners appointed to consider the draft charter for the proposed Gresham University in London have by their report made recommendations with respect to the reconstitution of the University of London, and to the appointment of a statutory Commission for that purpose.

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons in this present Parliament assembled, and by the authority of the same, as follows:—

1.—(1) There shall be a body of Commissioners styled the University of London Commissioners, and consisting, in the first instance, of the following persons, namely:—¹

(2) If and whenever any vacancy occurs among the Commissioners it shall be lawful for Her Majesty the Queen to appoint a person to fill the vacancy; but the name of every person so appointed shall be laid as soon as may be before both Houses of Parliament.

2.—(1) The powers of the Commissioners shall continue until the end of the year 1896, and no longer; but it shall be lawful for Her Majesty the Queen, from time to time, with the advice of Her Privy Council, on the application of the Commissioners, to continue the powers of the Commissioners for such time as Her Majesty thinks fit, but not beyond the end of the year 1897.

(2) The Commissioner first named in this Act shall be the Chairman of the Commissioners, and in case of his ceasing from any cause to be a Commissioner, or of his absence from any meeting, the Commissioners present at each meeting shall choose a chairman.

(3) The powers of the Commissioners may be exercised at a meeting at which three or more Commissioners are present.

(4) In case of an equality of votes on a question at a

¹ Here follows a blank space for the names of the Commissioners.

meeting, the chairman of the meeting shall have a second or casting vote in respect of that question.

(5) The Commissioners shall have a common seal which shall be judicially noticed.

(6) Any act of the Commissioners shall not be invalid by reason only of any vacancy in their body; but if at any time, and as long as, the number of persons acting as Commissioners is less than four, the Commissioners shall discontinue the exercise of their powers.

3.—(1) The Commissioners shall make statutes and ordinances for the University of London in general accordance with the scheme of the report hereinbefore referred to, but subject to any modifications which may appear to them expedient after considering any representations made to them by the Senate or Convocation of the University of London or by any other body or persons affected.

(2) In framing such statutes and ordinances the Commissioners shall see that provision is made for securing adequately the interests of non-collegiate students.

(3) All such statutes and ordinances shall be laid forth with before both Houses of Parliament, and shall come into operation on the expiration of forty days after they have been so laid, and shall have effect as if enacted by this Act, but shall be subject to alteration in manner provided by such statutes and ordinances.

4. This Act may be cited as the University of London Act, 1895.

CHOLERA.

It will be remembered that there were reports of a somewhat severe outbreak of cholera among the Japanese troops engaged in the Chino-Japanese war. The official returns show that the total cholera mortality of the outbreak in question among the Japanese at the Pescadores Islands, between March 26th and April 24th amounted to 1300. There are still a few sporadic cases reported daily, but the epidemic—which at one time gave the Japanese authorities some anxiety—is believed to be at an end. There is no doubt that cholera has broken out and is very prevalent at the present time at Mecca and among the villages and pilgrim caravans. The outbreak in Mecca has given rise to an average daily mortality of twenty-five; and the Sanitary Board at Constantinople is busy devising precautionary measures against the spread of the disease by the returning pilgrims. The number of Egyptian pilgrims this year is said to be much smaller than usual. There would appear to have been a revitalisation of cholera at a number of places this spring, for the Official Gazette of Madrid has imposed quarantine on arrivals from Hong-Kong, Haiphong, San Nicholas, San Pedro, and Jeddah, all of which are notified as being affected with cholera.

There have been occasional reports of the arrival of vessels alleged to be cholera-infected at Gravesend from abroad. One such vessel arrived the other day from the River Plate, on board of which a fatal case of cholera is stated to have occurred on March 16th last, followed by four other cases of a slight but suspicious character, all of which however recovered.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6494 births and 3585 deaths were registered during the week ending May 11th. The annual rate of mortality in these towns, which had declined in the nine preceding weeks from 35.0 to 17.5 per 1000, was last week 17.7. In London the rate was equal to 16.6 per 1000, while it averaged 18.4 in the thirty-two provincial towns. The lowest rates in these towns were 12.9 in Swansea, 13.5 in Brighton and in Hull, 13.6 in Sunderland, and 14.1 in Gateshead; the highest rates were 23.0 in Liverpool, 23.6 in Burnley, 23.9 in Halifax, 24.5 in Preston, and 25.8 in Plymouth. The 3585 deaths included 351 which were referred to the principal zymotic diseases, against 327 and 305 in the two preceding weeks; of these, 83 resulted from measles, 81 from whooping-cough, 65 from diphtheria, 60 from diarrhoea, 31 from scarlet fever, 31 from "fever" (principally enteric), and not one from small-pox. No fatal case of any of these diseases

occurred last week in Croydon or in Swansea; in the other towns they caused the lowest death-rates in Oldham, Gateshead, and Derby, and the highest rates in Cardiff, West Ham, Bolton, and Plymouth. The greatest mortality from measles occurred in Cardiff, Manchester, West Ham, Bolton, Newcastle-upon-Tyne, and Plymouth; and from whooping-cough in Salford and Burnley. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 65 deaths from diphtheria included 38 in London, 6 in West Ham, 4 in Birmingham, 3 in Wolverhampton, and 3 in Liverpool. No fatal case of small-pox was registered either in London or in any of the thirty-two large provincial towns. There were 33 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, May 11th, against 35, 37 and 34 at the end of the three preceding weeks; 6 new cases were admitted during the week, against 4, 12, and 8 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1438, against 1514, 1469, and 1413 on the three preceding Saturdays; 179 new cases were admitted during the week, against 162, 132, and 107 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 341 and 290 in the two preceding weeks, further declined to 247 last week, and were 86 below the corrected average. The causes of 52, or 1.5 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Nottingham, Bradford, Hull, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Bolton, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20.6 and 20.9 per 1000 in the two preceding weeks, declined again to 18.7 during the week ending May 11th, but was 1.0 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16.2 in Dundee and 16.5 in Edinburgh to 24.0 in Perth and 27.8 in Leith. The 540 deaths in these towns included 30 which were referred to measles, 17 to whooping-cough, 5 to diarrhoea, 3 to "fever," 2 to small-pox, 2 to scarlet fever, and not one to diphtheria. In all, 59 deaths resulted from these principal zymotic diseases, against 73 and 71 in the two preceding weeks. These 59 deaths were equal to an annual rate of 2.0 per 1000, which slightly exceeded the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 32, 26, and 27 in the three preceding weeks, rose again to 30 last week, of which 9 occurred in Leith, 8 in Edinburgh, 5 in Aberdeen, and 4 in Paisley. The deaths referred to whooping-cough, which had been 24 and 17 in the two preceding weeks, were again 17 last week, and included 12 in Glasgow, 2 in Leith, and 2 in Greenock. The 3 fatal cases of "fever" also corresponded with the number in the preceding week. The deaths from scarlet fever, which had been 4, 3, and 7 in the three preceding weeks, declined to 2 last week, both of which occurred in Glasgow. Of the 2 fatal cases of small-pox 1 was registered in Edinburgh and 1 in Glasgow. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 145 and 124 in the two preceding weeks, further declined to 98 last week, and were 15 below the number in the corresponding week of last year. The causes of 33, or more than 6 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27.0 and 27.3 per 1000 in the two preceding weeks, further increased to 27.4 during the week ending May 11th. During the past six weeks of the current quarter the death-rate in the city has averaged 30.7 per 1000, the rate during the same period being 18.0 in London and 19.0 in Edinburgh. The 184 deaths registered in Dublin during the week under notice showed a very slight increase upon the number in the preceding week, and included 7 which were referred to the principal zymotic diseases, against 5 and 7 in the

two preceding weeks; of these, 3 resulted from whooping-cough, 2 from diarrhoea, 1 from small-pox, 1 from "fever," and not one either from measles, scarlet fever, or diphtheria. These 7 deaths were equal to an annual rate of 1.0 per 1000, the symtotic death-rate during the same period being 1.7 in London and 2.1 in Edinburgh. The fatal cases of whooping-cough, which had been 1 and 4 in the two preceding weeks, were 3 last week. The 2 deaths from diarrhoea exceeded the number in any recent week. One fatal case of small-pox was recorded during last week, making 10 deaths from this disease within the city during the current quarter. The 184 deaths registered in Dublin last week included 21 of infants under one year of age and 50 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons corresponded with the number in the preceding week. Six inquest cases and 5 deaths from violence were registered; and 85, or nearly one half, of the deaths occurred in public institutions. The causes of 11, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-COLONEL O'DWYER has embarked for Halifax to relieve Surgeon-Colonel Archer as Principal Medical Officer of the Command. Brigade-Surgeon-Lieutenant-Colonel Grose has been transferred from Belfast to Edinburgh. Surgeon-Major Michael and Surgeon-Captain Gray have arrived from Egypt on completion of a tour of service. Surgeon-Captain Hall has embarked for Sierra Leone. Surgeon-Captain Keatly has been posted to Ireland; Surgeon-Captain Corcoran to Colchester; and Surgeon-Captain Macdonald to Portsmouth.

ARMY MEDICAL STAFF.

Surgeon-Colonel Edward C. Markey, C.B., to be Surgeon-Major-General, vice J. Davis, retired. Brigade-Surgeon-Lieutenant-Colonel William E. Riordan to be Surgeon-Colonel, vice E. C. Markey, C.B. Brigade-Surgeon-Lieutenant-Colonel Philip Le Feuvre Kilroy retires on retired pay. Surgeon-Lieutenant-Colonel John G. Williamson to be Brigade-Surgeon-Lieutenant-Colonel, vice W. E. Riordan.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments are announced:—26th Bombay Infantry: Surgeon-Captain Sprague to officiate in Medical Charge, vice Surgeon-Captain Heath; Surgeon-Colonel Geoffrey Hall to take up the duties of the Inspector-Generalship of Gaols in the North-West Provinces; Surgeon-Captain E. Jennings, doing duty under the orders of the Civil Surgeon, Nagpore, to be Civil Surgeon of Betul, and to the Executive and Medical Charge of the Betul Gaol; Surgeon-Major J. L. Poynder, Civil Surgeon, Sambalpur, to officiate as Civil Surgeon, Raipur; Surgeon-Captain W. D. Sutherland, Civil Surgeon, Damoh, to officiate as Civil Surgeon, Sambalpur, and to the Executive and Medical Charge of the Sambalpur Gaol.

MILITIA.

3rd and 4th Battalion the South Staffordshire Regiment: Lieutenant A. G. Mossop to be Captain.

YEOMANRY CAVALRY.

Hampshire (Carabiniers): Surgeon-Captain G. F. A. England, M.B., resigns his commission; John Frederick Gordon Dill, M.D., to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Aberdeenshire: John Marnoch, M.B., to be Surgeon-Lieutenant. 3rd Durham (Western Division, Royal Artillery): Surgeon-Lieutenant J. Macdonald, M.B., resigns his commission. Rifle: 20th Middlesex (Artists'): Surgeon-Lieutenant H. D. Brook to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The Woolwich Company: Surgeon-Lieutenant P. O. Haynes to be Surgeon-Captain.

CHITRAL.

The Anglo-Indian papers contain, of course, a large amount of intelligence about the garrison of Chitral and the expeditionary field forces, but the various telegraphic sum-

maries forwarded to this country have anticipated their news and tended to render the descriptive accounts furnished by correspondents with the columns in the field stale reading. The chief points which strike us in connexion with the expedition are the highly commendable promptitude with which the forces were mobilised and took the field; the very arduous nature of the undertaking in the way of the natural obstacles and topographical difficulties that had to be overcome; the self-reliance and fine military qualities of the troops composing the native army; the brilliant marches under the leadership of such men as Colonel Kelly and Captains Borrodalle and Stewart—men who were but yesterday unknown, as it were, and but a sample, we hope and believe, of that ability and pluck to be calculated upon as always to be found among British officers; the heroism of the Chitral garrison, and, we may add, the exhibition of gallantry and devotion on the part of medical officers. Taking it altogether, we may fairly say that this Chitral affair has been a good business; it has raised our prestige in India and on the Continent and shown the strength of our position in the East, and it has impressed people generally with the admirable behaviour of our troops, European and native, of all ranks, and of the good feeling and faithful services of those of our allies who, like the Khan of Dir, gave their aid to the cause in which we were engaged.

THE CHITRAL EXPEDITION: MEDICAL ARRANGEMENTS.

Up to the present time, as far as we have seen, no mention has been made as to the manner in which the duties of the medical department have been carried out during the little war which is just now coming to a close on the northern frontier of India. Individual acts of heroism have been mentioned, such, for instance, as that of Surgeon-Captain H. F. Whitchurch of the Indian Medical Service, and the gallantry and fortitude, under very trying circumstances, of the political agent, Surgeon-Major G. S. Robertson, C.S.I., also of the Indian Medical Service. These officers will no doubt have such honours and rewards bestowed upon them as may seem fitting to Her Majesty and her advisers for such distinguished conduct. The daily and weekly press have, however, been silent as to the excellences or imperfections of the general arrangements made for the carriage and treatment of the sick and wounded of the expedition. We have reason to believe that the mule transport for the field hospitals (which in India includes the bearer companies) was taken from the medical department at Nowshera, and that bullock-carts were supplied instead. This, we understand, was done by order of the general officer commanding in consequence of the paucity of transport animals, and of the imperative necessity of forwarding supplies of food and ammunition. We should like to know how the field hospitals fared under these circumstances, as bullock-carts are absolutely useless in such a country as the army had to traverse. The regulations lay down that the medical transport shall not be taken away or used for any other purpose unless under the authority of the general officer commanding. We look forward with interest to an account of how the field hospitals fared on the road to Chitral under these circumstances. It is quite right, no doubt, that the general officer commanding should possess and exercise this authority in cases of imperative necessity, but we think that nothing short of this should justify the commander of a field force in using medical transport for other purposes, seeing that it enormously increases the difficulties of the medical service, and might indeed, as it has done before now, bring the medical arrangements to a complete standstill.

A CONGRESS OF MILITARY HYGIENE.

A correspondent of the *Morning Post* lately called attention to the desirability of holding a congress in this country devoted solely to questions relating to military hygiene, and sketched a programme—in bare outline, of course—of the subjects that might be taken up for consideration and discussion at such a meeting. He advocates that a congress of this sort, organised under favourable patronage, should be held at some large military centre in this country, and thinks that members of military medical services of different nations and others interested in the subject would be led to take part in it, with much practical advantage to all concerned. The general feeling is, perhaps, that medical and other congresses have been rather overdone of late, that subjects cannot be thoroughly or always advantageously considered at them, that too much is attempted, which is

creative of a "rush," that too many subjects are taken up, and that it is difficult to exclude faddists. Be this as it may, there is no doubt that the institution of a military section at such congresses is not altogether satisfactory. There are, no doubt, a sufficient number and variety of important matters to be considered in connexion with modern warfare to occupy the attention of a congress devoted exclusively to questions of military hygiene and medicine.

VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the under-mentioned officers:—*North-Eastern District: Rifle: 2nd Volunteer Battalion the East Yorkshire Regiment: Surgeon-Captain Alexander Theodore Brand, M.D. Scottish District: Rifle: 1st Volunteer Battalion the Royal Scots Fusiliers: Surgeon-Major William Wilson; Surgeon-Major William Frew, M.D. 3rd (The Buchan) Volunteer Battalion the Gordon Highlanders: Surgeon-Captain James Stephen, M.D.*

SOUTHAMPTON AND THE TROOP TRANSPORT SERVICE.

According to a Reuter telegram, the whole of the transport service will in future be carried out at Southampton instead of at Portsmouth. The facilities afforded at Southampton, its nearness to Netley Hospital, and the efficient manner in which the embarkation of troops has been carried out at the port have led the authorities to decide that next season the transports will embark troops in the Empress Dock and disembark there all invalids, time-expired men, and others returning home.

THE HEALTH OF CALCUTTA.

Scarcely has the news reached us that small-pox is epidemic in Calcutta than advices come to hand stating that typhoid fever has broken out among the Europeans of that city. The fever, it is feared, will take an epidemic form, and a scare may possibly be created as cholera is said to be on the increase. The absence of heavy rains and consequent dearth of water is probably in a great measure responsible for this state of things.

EXTENDED TENURE OF APPOINTMENTS.

Surgeon-Major-General J. Warren has, it is stated, been granted an extension of the tenure of his appointment of Principal Medical Officer, Bombay, until July 6th, 1896. The frequency with which these extensions of service occur in the senior administrative rank of the medical department must, we imagine, seriously affect the prospects of many medical officers by impeding the flow of promotion.

THE WAZIRISTAN CAMPAIGN.

Among the names of political and military officers that have been mentioned in General Sir William Lockhart's despatches concerning the recent campaign in Waziristan are the following medical officers:—Surgeon-Colonels Spencer and Bockey and Surgeon-Major Shearer.

Correspondence.

"Audi alteram partem."

MEDICAL QUESTIONS AND THE "ECHO."

To the Editors of THE LANCET.

SIRS,—You having alluded to the correspondence on medical questions conducted in the columns of the *Echo*, I shall be exceedingly obliged if you will give me the opportunity of disclaiming identity with the person who, under the name of "Lennox," is responsible for the answers. This is not a case of *qui s'accuse s'accuse*, for it has been a subject of constant inquiry from my medical friends for many years, and I am still frequently receiving letters from patients introducing themselves to me in the belief that I am the individual whose aid they have sought through the columns of this paper. I frequently applied in vain to the editor to publish my disclaimer of identity, and only on the threat of legal proceedings succeeded at last in obtaining the following, under date of Dec. 16th, 1892: "Dr. Lennox Browne wishes us to say that he is not the 'Lennox' who answers queries in this column. We willingly comply with his request for two reasons—first, because it pleases him, and, secondly, because it is rather advantageous than otherwise that our readers should know that the correspondent

'Lennox' is not Dr. Lennox Browne." The annoyance, however, still continues, and I may add that the real name of the person bears no resemblance to the pseudonym, nor is he, according to the name given in a published book on deafness by "Lennox," to be found in the Medical Directory.

I am, Sirs, yours faithfully,

LENNOX BROWNE.

Mansfield-street, Portland-place, W., May 13th, 1895.

A PREVENTIVE OF HYDROPHOBIA.

To the Editors of THE LANCET.

SIRS,—In the course of a conversation which I had with an intelligent Hausa native a few days ago I was informed that the following method is adopted here with the view of preventing hydrophobia following the bite of a rabid dog or other animal. When a person is bitten by a dog supposed to be suffering from rabies the animal is instantly caught, killed, and cut open, the liver is taken out and slightly browned by being held to the fire, after which the whole of the organ is eaten by the patient. I have made further inquiries, and I find that it is generally believed here that this treatment in many instances prevents the onset of the disease. If it is so, it is interesting to notice the similarity which exists between it and that of M. Pasteur.

I am, Sirs, yours faithfully,

THOMAS J. TONKIN, L.R.C.P. & S. Edin.,

Medical Officer, Hausa Association, Soudan Expedition, Kano, Hausa State, Western Soudan, Feb. 6th, 1895.

"THE POSSIBLE ANTAGONISM BETWEEN MALARIA AND PHTHISIS."

To the Editors of THE LANCET.

SIRS,—At the Indian Medical Congress Mr. Ardaseer Dossabhooy Cooper read a paper on the Possible Antagonism between Malaria and Phtisis.¹ He asserts that in 1811 it was put forth by Wells that malaria and phtisis were opposed to each other, and that M. Bedouine formulated the views that where malarial endemic fevers are prevalent phtisis is rare, and that phtisis is more curable in malarious regions than in others. The last Medical Report of the Surgeon-General of Trinidad completely disproves these formulated views. For the year there were 1452 cases of intermittent fever and 315 cases of remittent fever treated in the public hospitals of Trinidad. When we look under the heading of phtisis pulmonalis in the same report we find 430 cases recorded, with a mortality of 48 per cent. The following return of deaths during the year is instructive: dysentery and diarrhoea, 242; phtisis pulmonalis, 207; malarial fevers, 57. There were 13,092 patients under treatment. It is curious to note that there was only one case of rheumatic fever.

I am, Sirs, yours truly,

HENRY ALSTON,
Trinidad Medical Service.

April 20th, 1895.

ARE APOTHECARIES, OLD OR NEW, ENTITLED TO ADVERTISE?

To the Editors of THE LANCET.

SIRS,—I am prompted, along with many others whose professional interest will soon be vitally affected, to ask this difficult but very important question. We know that graduates and diplomates of the universities and colleges, whether they be also apothecaries or not, cannot advertise with impunity. Can more particularly the new L.S.A. only advertise his skill? I will briefly, with your permission, discuss the medico-legal arguments of this latter case.

An apothecary is licensed by a society which, by Act of Parliament dated 1815, can keep open shop for the retailing of drugs or other wares and for affording medical advice and treatment. He may argue from this that he can legally advertise the sale of his wares and also the sale of his services. It does not appear that the legal powers to retail and advertise have been repealed by subsequent Acts, although new privileges have been conferred. An L.S.A. only may contend that, not being a graduate or diplomate of other corporations, he need not concern himself with their ideas of conduct and etiquette, as they have no power to penalise

¹ THE LANCET, Jan. 19th, 1895.

him. Further, that the Apothecaries' Society itself, even if it felt so disposed—which is most improbable—cannot legally prevent its licentiates from advertising in whatever manner they think proper. It cannot withdraw without sufficient cause the power which it has once legally conferred. He may also assert that he can advertise in defiance of the General Medical Council, while admitting that he is under their control on other matters of infamous conduct, for no court of equity would allow the Council to declare under one Act of Parliament as "infamous conduct" what is especially authorised by an unrepealed Act. Again, although the General Medical Council can erase the name of an apothecary possessing another qualification who advertises, it is not for the act itself, but for the violation of his agreement with the body who granted the other diploma. It seems as if these contentions are valid, otherwise how can we account for the painful facts already only too evident. The magnates of the Council and other distinguished upholders of professional ethics have only to turn their heads slightly to one side to observe the establishments of the new L.S.A.'s as they roll down the thoroughfares of towns in their carriages. These gentlemen can read on the shop and dispensary windows of their apothecary *confreires* such announcements as "Ears syringed, 6d." They can see degraded scales of fees unblushingly exhibited, and, worse than all, in close juxtaposition, the words, "Dr. —, Physician and Surgeon." We are thus forced to the conclusion that the powers that be cannot legally interfere to prevent this. When the claims of the Apothecaries' Society to full professional recognition were under discussion much opposition was raised that was founded on the shadows of professional jealousy, instead of the solid objection of being an advertising corporation; the medical press generally advocated these claims, ignoring the advertising feature. Now it was not on account of jealousy or any supposed educational superiority that some prescient ones looked askance on this unholy alliance between advertisements, trade, and profession. The triple qualification of the Apothecaries' Society certainly equals, if it does not excel, the conjoint qualification of the Colleges; and the apothecary is equally as much entitled to the titles Physician, Surgeon, and Doctor as the licentiates of the Colleges. Formerly the single apothecary acted as a druggist who also prescribes and visits, and was consequently regarded by the public as an inferior mongrel practitioner. The advertisement of his wares and services did not, as it now will, degrade the profession as a whole. Later in the century, with the establishment of the Pharmaceutical Society, the apothecaries gradually withdrew from the advertising branch until, in 1886, perhaps not 3 per cent. of L.S.A.'s adopted that style of practice. At this date Apothecary and Licentiate Physician were practically synonymous titles, either or both being held by surgeons indifferently. As long as the Apothecaries' Society could only grant a single qualification its licentiates were almost compelled to become surgeons, and consequently submit to the dicta of the Colleges and Council in matters of conduct and etiquette. The old order of things is changing, and that steadily for the worse. Owing to the hostility of the Royal College of Physicians of London to the modest claim of the Apothecaries' Society for admission to the fold the latter played for a higher prize and, as some of us minors foresaw, gained it. We saw that Parliament would in spite of opposition grant the Society power to confer a triple qualification and thus make it more powerful than, and independent of, either or both Colleges combined. If with the acquisition of independence and new privileges the old privileges of advertising and trading had simultaneously been withdrawn all would have been serene. One of the results is already becoming manifest. Many students are now taking the Apothecaries' Society's diploma, and that only, so as to be enabled to become advertising doctors, physicians, and surgeons. The extra privilege is very alluring to a large class, so that shortly we may expect the Apothecaries' Society to absorb the lion's share of examination fees for its diploma. Are the new L.S.A.'s going to drag down with them the science and art of medicine to the trade level of quackery? If so, then the "infamous conduct" clause is almost a dead letter. Now is the time (before many more new L.S.A.'s are admitted) for the General Medical Council, if it can, to declare advertising infamous conduct when practised by apothecaries. The Council devotes the major portion of its time in

punishing a few paltry cases of covering, which are of no moment to the profession, whilst wholesale degradation of it seems scarcely worth their notice. Three advertising L.S.A.'s will damage the prestige of the profession more than a few thousand coverers. It will be interesting to see if any of the three gentlemen who were returned as direct representatives will really represent the opinions of the vast majority of their constituents (at the forthcoming meeting of the Council) on this subject—viz., exhibition of scales of fees &c. on dispensary shop windows by apothecaries.

I am, Sirs, yours obediently,

May 6th, 1895.

ETHICS.

* * Our correspondent complains that the holders of the new L.S.A. give less consideration to the ethical standards of the profession than other licentiates or graduates, and that the Apothecaries' Society is either unable or unwilling to administer discipline in the case of such unworthy licentiates. We think he is a little hasty in bringing this accusation against the new licentiates. As far as our experience goes—and it is considerable—the new apothecaries are not so much in fault here as licentiates of certain colleges with royal titles, and even graduates of famous universities, who are, in the great majority of cases, allowed to transgress all professional standards of taste without serious remonstrance from their authorities. The fact is that the colleges and the universities have winked at these evils and errors in their members till they have become almost established. They show a cowardice in using their disciplinary powers and a disposition to save themselves trouble and expense by referring complainants to the General Medical Council. The Council is not meant to be the first court of judgment in such matters and it is not likely to relieve the medical bodies of the responsibility of exercising their powers. After the latter bodies have done their duty and failed to remedy the evils in question it will become the duty of the General Medical Council to consider what else can be done to avert the degradation of the profession.—ED. L.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Ingleby Lectures.

THE first of a series of three lectures under the conditions of the Ingleby Trust was given by Mr. Gilbert Barling at Mason College on the 9th inst. The subject chosen was Appendicitis and Perforating Ulcer of the Stomach and Duodenum. The audience was select and appreciative. From the attention drawn so largely to this subject of late years in the literature of the profession, and from Mr. Barling's practical knowledge of these conditions, an interesting account is expected, the fulfilment of which, no doubt, will be amply realised.

Aggravated Assaults.

Cases of assault and aggravated cruelties are rife in our midst at the present time. They show no signs of abatement, in spite of the educational influences of the period. For pouring carbolic acid upon his wife, and for spending the greater part of his time in debauchery, drinking, and horse-racing, a man was sentenced recently to three months' imprisonment and the wife was granted a separation order. This combination of cause and effect does not appear to have much deterrent influence upon the many who spend their lives in similar degrading conditions and who in the midst of populous towns, with numerous counteracting advantages, forget the main principles which should bind society in mutual obligations of improvement and progress.

A Novel Invitation.

The Health Committee have thrown open the small-pox hospital for inspection, and intimated their willingness for persons to go over the premises. At first sight the acceptance of the invitation would seem to be a questionable act of courtesy, but fears are removed from timid minds by the knowledge that there are no patients at present in the building. The committee, no doubt, seek to justify their prudence by the display of the means within their power for combating any emergencies which may arise in this direction.

Black Country Pursuits.

The depression in trade gives rise to much idleness and indifference. "That Satan finds some mischief still" is exemplified in the manner in which the unemployed find occupation for their leisure. It has been the custom for some of the residents in a particular locality of this district to assemble on the first Sunday in the month of May with dogs, and to make a grand parade of the respective qualities of these canine pets. That much consideration is expended upon the training and cultivation of the various attributes of these animals was known to the readers of *Punch* many years ago, when a father, being seized on the leg by a dog, was exhorted by his son to hold on, as it would be the making of the pup. Of course, these displays lead to fighting, betting, and demoralisation of human as well as canine instincts. On this particular occasion several of the principals were fined 20s. and costs as the outcome of their cruel propensities.

May 14th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Plumbers' Work and Public Health.

CONCURRENTLY with the proceedings of the Sanitary Congress, sketched in my last communication, the district councils for the registration of plumbers in the northern and midland counties held a conference in the town hall. Mr. John Holden, architect, presided, and said the plumber was much abused, sometimes with good reason, but often unjustly, the general contractor or "speculative owner"—a euphemism for the jerry-builder—arranging the contracts so low that the work could only be done in "a certain manner." After twenty years' constant pressure exercised by the Sanitary Association and by the Manchester Society of Architects, jerry-building had, however, received a severe check from the operations of the Building By-laws. Moreover, technical education had already produced a great improvement in plumbers' work. One of the greatest difficulties was the demand for cheap or low-rented houses. For the last forty years rents had been going down, or what was the same thing, the requirements of the public had been going up, and a £30 house now was very different from a £30 house of forty years ago, and practically small property had passed out of the hands of first-class builders, who could not make it pay, into the hands of speculators. "Depend upon it," he said, "the demand of the public would be met by a corresponding class of workmanship." This is no doubt true, but the sins of the plumbers have been by no means confined to cheap property.

Cold Air Stores.

On the 23rd ult. an important step in the hygienics of Manchester was marked by the opening of the Corporation Cold Air Stores, which have been built close to the abattoirs. They are believed to be second to none in the country, and, as the chairman said, are a great credit to the engineer, Mr. Bannister, who had designed and carried out the works to the entire satisfaction of the Markets Committee, at a cost of a little over £75,000. The building covers an area of about 2000 square yards, and comprises a basement, ground floor, and three upper floors, with provision and strength for a fourth floor when required. It is fitted with hydraulic lifts and with the best appliances for dealing with freshly killed meat, which can be quickly cooled, chilled, and set during the summer months, whereby its market value is greatly increased. There are no pipes and no machinery in the storage chambers. Air is drawn from the rooms and returned after passing through the refrigerator, where it is "washed, cleansed, purified, cooled, and dried." No snow, fog, or damp is therefore produced, and any temperature can be maintained between 40° and 15° F. They will be used also for the preservation of game, fish, cheese, butter, fruit, and vegetables. There is sufficient space for the storage of 120,000 sheep. These stores will prevent enormous losses of perishable food and will be a great benefit both to the traders and the public.

Presentation to the Rev. J. Henn.

The Manchester and Salford Hospital Saturday and Sunday Fund has been in existence for twenty-five years. Its establishment in 1870 was due in great measure to the exertions of

the Rev. John Henn, who has been up to the present its indefatigable secretary. Some friends of the movement thought that such an opportunity of recognising the long-continued and disinterested labours of Mr. Henn should not be lost, and on the 23rd ult. he was presented with a large piece of silver plate and a cheque. In acknowledging the gift Mr. Henn gave some interesting information as to the remarkable spread of the movement, not only here, but among English-speaking people abroad.

Owens College: Opening of the Schorlemmer Laboratory.

An interesting gathering took place on the 3rd inst. at the opening, by Dr. Ludwig Mond, of the Schorlemmer Laboratory for Organic Chemistry, together with a large laboratory for medical students. After Professor Schorlemmer's death it was felt that such a laboratory would be his best memorial, and a subscription list was opened, which was well responded to both in this country and in Germany. For many years there had been a rapid growth of the chemical department of the College, and the laboratories, originally designed for 100 students, had long been overcrowded. In the session 1890-91 there were 120 students, in the present month they numbered 205, and the council some time ago became convinced of the need for extension. They, therefore, accepted the Schorlemmer Fund of £2500, and instructed Mr. Waterhouse to prepare plans for the special laboratory and for one for elementary students. These are arranged in one building, the upper part of which is the Schorlemmer laboratory, designed to accommodate a professor, two demonstrators, and thirty-six students. It is fitted up in the most complete manner, with every requisite for the important work to which it is dedicated. The lower laboratory will accommodate forty-five students, and the fittings are similar to those designed many years since by Sir H. Roscoe. The total cost of the building has been £4800. At a meeting in the chemical theatre, at which Sir H. Roscoe presided, Professor Dixon said he had received many messages and letters from home and abroad regretting absence and wishing prosperity to the new laboratory. He desired, on behalf of his colleagues and himself, to express their admiration for the noble simplicity of Schorlemmer's life and character. No one could more truly be said to have lived for the sake of his work, which included research of the highest order. Sir H. Roscoe stated that Schorlemmer came to him in 1859 and remained his faithful and intimate friend for thirty-four years. His investigations into the constitution of the hydrocarbons marked an era in modern organic chemistry, and, while his work had a purely scientific value, it enabled others to build up an industrial structure the value of which was measured by millions of pounds and employed thousands of men. He lived and died a poor man, though he might have amassed a large fortune. Dr. Ludwig Mond, in the course of an interesting address, adverted to the fact of this being the first laboratory in England devoted to organic chemistry, and of Owens as the only college in the country having a professor of that science. (The chair is now filled by Professor Perkin.) They must all regret that Schorlemmer had not such a laboratory at his disposal. His work had been singularly fruitful in clearing up and putting on a sound basis the theory of modern organic chemistry, called by him "the chemistry of the carbon compounds." If asked why a special laboratory and special professors were required for the study of that one element, one reason was the vast domain and immensely rapid increase of the science of chemistry as a whole. A stronger reason was that the methods of investigation and our way of mentally analysing those compounds differed considerably from those applied to inorganic chemistry. In organic compounds the percentage composition and physical properties told little of their chemical individuality and behaviour. They had to find out "how they were built up," and to do so had to break them down by degrees—to take them gradually to pieces. To make sure of the actual arrangement they had to put them together again and rebuild them from their proximate constituents. The methods employed in that work were entirely different from those of ordinary analysis. He said that for carrying on successfully the manufacture of artificial colours the chemist should be able to carry out independent original research. It was not the workman, it was not the foreman, it was the leading mind who directed the manufactory upon whom the success of an industrial enterprise depended—upon his thorough grasp of scientific principles and his trained habit of scientific thought. Dr. Mond looked forward in the near future to the making of morphine, quinine, and similar

bodies artificially, and to the synthesis of the ingredients of our daily food, such as sugar, starch, and gum. "But it was quite different with those important parts of our food which had been called the albuminous bodies. All we knew of them was their percentage composition, and that they contained the carbon atoms linked together, partly as in the fatty compounds and partly as in the aromatic bodies. The enigma of life could only be solved by the synthesis of an albuminous compound. Surely with such a prospect before them as the ultimate result of the pursuit of organic chemistry, no amount of work, no amount of thought, no amount of time and trouble devoted to that study would be too much if it was well employed in leading successfully to the great end in view, although the goal might not be reached for generations to come." Notwithstanding the anticipations of Kekulé and Professor Fischer of Berlin many of us are no doubt sceptical as to the organic chemists producing living protoplasm and solving the "problem of the origin of life."

Deterioration of Race in Lancashire.

The *City News* calls attention to the effect of mill life in lowering the physique of the workers, the men becoming "stunted and prematurely enfeebled." The heated and moist air of the mills where the working hours are passed and the too early employment of the children as half-timers are important factors in producing this result. Then, too, very early marriages, want of thrift, ignorance of domestic management and of the simplest cooking, in many cases alternate extravagance and privation, together with other causes, combine to bring about this disastrous effect. Football is immensely popular in Lancashire, but the teams are chiefly composed of imported Scotchmen who play the game while the natives look on and shout. The police force illustrates the same thing. Three policemen in Oldham had to be sworn in the other day, and none of them were townsmen. The chief constable said that few Oldham men came up to the standard of physique required, the country districts, Scotland, and Ireland furnishing most of the district police forces. In the well-to-do families of the manufacturing districts the girls are very often—one may almost say generally—taller and more finely developed than the young men. The latter go early to the office or the mill, while their sisters remain longer at school and when at home have a much better time than their brothers as to out-door amusement and exercise and as to their daily surroundings. On the other hand, the women and girls of the working classes do not show this superiority. They are as stunted, weakly, and even more anæmic than their feeble and ill set-up brothers. In our manufacturing towns the prospect for the race is undoubtedly bad, but something may be done in preventing too early employment of the children. With this question a provision of the Government Factories and Workshops Act Amendment Bill proposes to deal.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Glasgow University.

THE following appointments have been made by the University Court: Mr. Thomas Savill, M.D., to be Examiner in Clinical Medicine; Mr. H. E. Clark, M.R.C.S., surgeon to the Glasgow Royal Infirmary, to be Examiner in Clinical Surgery. Glasgow graduates will hear with regret of the retirement of Dr. Dickson from the chair of Divinity. Dr. Dickson has been a professor in the University for the long period of thirty-two years, and, in addition to his professional eminence, has been well known in all the faculties for the valuable service he has rendered as curator of the University Library. In this latter capacity he has compiled both a complete alphabetical catalogue and also a catalogue of subjects, thus much facilitating the work of students and others engaged in research. The nomination of Professor Wm. Macewen for the Fellowship of the Royal Society, whilst welcomed by the profession generally, is naturally the subject of special congratulation in the University of which he is a graduate and in which he occupies with so much distinction the chair of Surgery. Dr. Alfred Young, Demonstrator of Anatomy in the University, has been appointed Assistant to the Professor of Surgery in Anderson's College. At the annual dinner of

the University Conservative Club on the 2nd inst. the chair was taken by Dr. J. Yule Mackay, until recently Senior Demonstrator of Anatomy in Glasgow, and now Professor of Anatomy in University College, Dundee. Quite a gleom has been cast over the commencement of the summer session by the sad suicide of a young medical student. He had lately been very peculiar in his manner, and cut his throat whilst in a state of temporary insanity.

Glasgow Police Convalescent Home.

A house, to be used as a convalescent home for members of the force, has recently been taken at North Queensferry. It is to be under the direction of an association which has been formed amongst the police for purposes of mutual assistance, each member paying a small annual subscription and being entitled to the benefits of the home when these are needed. The institution of the home is mainly due to the initiative of Sheriff Gillespie of Dunfermline, who has generously undertaken to meet all expenses during the first two years.

Natural History Society of Glasgow.

At a meeting of this society on the 2nd inst. a paper was read by Dr. R. Broom on the Anatomy of a Four-winged Chick. Professor McKendrick, F.R.S., has been elected an honorary member of the society.

City Parochial Board, Glasgow.

Dr. William A. Mackay has been elected assistant medical officer. The board has granted an increase of £10 to the salary of each of the out-door medical officers.

Ambulance Work.

The Ambulance Company of the 3rd Volunteer Battalion Highland Light Infantry (the Blythswood) has passed a first-class examination after inspection by Surgeon-Major Jerome, A.M.S. The inspection was made the opportunity of bidding farewell to Surgeon-Lieutenant-Colonel Brodie, who has for twenty-six years been connected with the battalion and who has been appointed Brigade-Surgeon-Lieutenant-Colonel of the Clyde Brigade.—The Lord Provost of Glasgow presided at the recent distribution of certificates to the members of the ambulance class at Braco, Perthshire, and delivered an address on the value of ambulance training. Dr. McArthur, who has conducted the class, was on the same occasion presented with a handsome Gladstone bag by the members.

Glasgow Police Commission.

The commission has unanimously adopted the recommendation of the Health Committee to increase the salary of Dr. A. K. Chalmers, the junior medical officer of health, from £400 to £500 and that of Mr. Fyfe, the sanitary inspector, from £450 to £500. In his report to the Health Committee Dr. Ruesell gives an account of the spread of small-pox in the city, and instances one case in which the patient was not discovered until a month after he had sickened with the disease, during which time he had infected no less than nineteen other persons. Neglect in obtaining medical attendance in other cases also has led to limited outbreaks of the disease. Thus, four cases were recently removed from a house in the East-end where a girl had been ill with the disease for some weeks, but had never been seen by a medical man; and last month a child with malignant small-pox actually died in the waiting-room of one of the dispensaries, and in spite of all precautions six cases followed this one source of infection. Last week there were 72 cases in the hospital at Belvidere, but to-day the number has fallen to 64.

West of Scotland Convalescent Home.

The seaside home at Dunoon has been recently enlarged by the addition of a new wing which will add fifty beds to the 200 the home previously possessed. The cost of the new building, with furnishing &c., has been nearly £5000. At the inaugural ceremony Dr. Robert Perry, who has been examining medical officer since the home was started twenty-five years ago, stated that nearly 60,000 convalescents had been admitted during that period. The formal opening of the new wing was performed by Lady King, to whom, as well as to Sir James King, the home is much indebted for valuable assistance.

Glasgow Hospital for Skin Diseases.

At the thirty-fourth annual general meeting of the subscribers to this institution Professor McCall Anderson in submitting the medical report stated that during the past year 1348 new cases had been admitted to the hospital, and

102 had been sent to the wards for skin diseases in the Western Infirmary, making totals since the establishment of the hospital of 42,316 and 1836 respectively. The treasurer's report showed a balance of £8 10s. 5d. on the right side of the account. The hospital continues to be a much-appreciated clinical school for instruction in the diagnosis and treatment of diseases of the skin. Professor McCall Anderson is the senior physician, and is assisted by Dr. W. R. Jack and Dr. Forbes.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

A Case of Leprosy.

ABOUT three years ago a sensation was created in the neighbourhood of Lisburn when it was announced that there was a leper living with his family at Culcavey. The man had lived for seven years in India, where he probably acquired the malady. As the people near Lisburn, where he lived, objected to his presence, after considerable discussion apartments were provided for him in the rear of the workhouse in Lisburn, where the man was located and where he died on May 7th. His mother and brother reside in Belfast. No person was infected with leprosy through contact with him.

Queen's College, Belfast.

At the general class examination, held at the close of the winter session, prizes were awarded as follows:—*Zoology*: Senior Division—W. A. Rice. Junior Division—John Adams, M. L. Rowans, B. A., and W. D. Hamill. *Systematic Anatomy*: Senior—David Fleck. Second Year—A. B. M'Master. First Year—R. A. L. Graham and G. H. Grills. *Practical Anatomy*: Senior—A. L. M'Cully and David Fleck. Second Year—A. B. M'Master and G. C. R. Harbinson. First Year—R. A. L. Graham. *Physiology and Histology*: Senior Class—A. L. M'Cully and R. W. G. Stewart. Junior Class—J. W. D. Megaw and J. W. Brown. *Practical Physiology and Histology*: G. A. Hicks, A. L. M'Cully, R. W. G. Stewart, and Henry Hanna, B.A. *Medicine*: R. W. G. Stewart. *Surgery*: Second Year—W. J. MacKeown, B.A., and W. A. Osborne. First Year—R. J. Johnstone, B.A., and W. M. Spiller, equal, and S. T. Beggs. *Materia Medica and Therapeutics*: C. E. M'Dade, B.A., and J. A. C. Doonan (non-matriculated). *Midwifery, Gynaecology, and Diseases of Children*: Senior Division—S. T. Beggs. Junior Division—W. A. Osborne and F. T. Heron. *Practical Chemistry*: R. A. L. Graham; A. V. Johnston and Arthur Martin, equal, and David Brown.

Boating Accident at Fair Head.

Another sad boating accident has occurred on the treacherous northern Irish coast. It seems that a boat belonging to Mr. Moore, cashier at the Northern Bank, Ballycastle, broke adrift from her moorings in Ballycastle Bay, and was picked up in Cushendall. On Saturday evening, May 11th, Mr. Moore, Mr. Sparrow (also of the Northern Bank), and Mr. T. Hay (son of the late Sir Arthur Graham Hay, Bart.) left Ballycastle for Cushendall, to bring back the boat. They had got as far as Fair Head on their return home, when at 10 p.m. the boat, struck by a heavy squall, foundered, leaving all three occupants to struggle home. Mr. Moore alone managed to reach a rock, where for a time he lay unconscious; but, recovering, was able to swim ashore, and reached Ballycastle at 3 o'clock on Sunday morning. Search parties went out in quest of the two missing men, who have not yet been found. The boat was picked up off Torr Head on Sunday afternoon by the ss. *Gannet*; she was found keel uppermost, with masts and sails floating alongside. The sails were all made fast and so they could not part from the boat. She was a good deal damaged.

The Belfast Asylum.

At a meeting of the board of governors held on May 13th the visiting committee reported that the dormitory accommodation was overcrowded. Not only were the sleeping-rooms overcrowded, but actually bedsteads were set up in several of the corridors. They thought that some effort should be made without delay to remedy this unsatisfactory arrangement. Dr. Merrick, medical superintendent, reported that there were 768 cases resident, while the normal accommodation was only for 400 cases—a very overcrowded condition. The admission-rate continues to increase. Since the opening of the year 95 cases were admitted, as compared with 64

cases up to the same date last year; while even last year there was a material increase in the number of admissions.

The Sewerage System for Purdysburn.

The subcommittee appointed to consider the system of sewerage proposed to be adopted at the new Purdysburn Asylum report that there are immense difficulties in the way of connecting the sewers with the Belfast City system, as also in making a sewage farm, and advise that the system recommended by their architect, Mr. Jackson—viz., precipitation and filtration—should be carried out and the clarified effluent be discharged over the grounds, by which the possibility of any interference with the water of the burn is avoided. They further advise that Mr. Jackson should be instructed to keep the main drain from Purdysburn House at as high a level as possible in order that all land available may be used for the sewage effluent. This report was adopted at the meeting of governors.

The Care and Maintenance of Harmless Lunatics.

For some time past a contest has been waged between the governors of the Cork Lunatic Asylum and the Poor-law guardians as to which board is responsible for the care and maintenance of harmless lunatics. A large number of the latter, amounting at present to as many as 150, have for years past been provided for in the Cork Workhouse. As a sort of compromise it was some time ago arranged that the authorities of the asylum should take over from the guardians any of those poor patients whose mental condition was not so hopeless as to preclude the possibility of cure. Some so sent to the asylum were promptly returned to the guardians, as the medical superintendent of the asylum reported that they did not come within the terms of the agreement. Apparently there was a conflict of opinion between some of the medical gentlemen attached to the two institutions, and as they and everyone else realised that a game of shuttlecock could not be played with some of the most helpless members of the human race matters have necessarily come to a climax. Accordingly, the guardians have forwarded to the Lord Lieutenant a carefully prepared memorial, in which they submit that it is the duty of the governors to take into the asylum all classes of the lunatic poor, whether curable or not, provided sufficient accommodation exists in the asylum. If it should be found that the asylum is not large enough for the purpose, the memorialists urge his Excellency to put in force certain statutes which they say empower him to compel the governors to provide the requisite accommodation either by additions to the existing establishment or by the erection of a separate one. The Under Secretary to the Lord Lieutenant forwarded the memorial to the governors for their observations, and in an accompanying letter stated: "His Excellency further desires me to inform you that he is advised that the District Lunatic Asylum is the institution primarily responsible for the maintenance of the lunatic poor of the district if vacancies can be found therein for their reception, and that the law does not draw a distinction between the different classes of lunatics in fixing the means for their maintenance." Whilst the memorial was under the consideration of the asylum board the medical superintendent, in reply to one of the governors, stated that according to the rules of the Board of Control they have accommodation for 1191, and that as a matter of fact they have sixty over and above that number in the asylum at present. He further added that he had procured returns from the seventeen workhouses in the county of Cork, showing that in these institutions there are 490 inmates mentally afflicted, including idiots, imbeciles, and chronic lunatics. Finally, it was decided that the memorial should be printed for circulation amongst the governors and a special meeting held to consider the whole question.

The Battle of the Clubs at Cork.

I mentioned in a previous letter that Cork is threatened with the formation of a commercial provident dispensary. Since then the local agent has obtained an interview with the committee of the profession, and had an opportunity of explaining the manner in which it is proposed to work the dispensary. He produced a copy of the printed rules, from which it was evident that there is no wage limit and that a member might live at any distance he thought fit from the residences of the medical officers. Except in comparatively few cases there is no medical examination of members on admission, and as the three farthings a week received by the medical officer from each adult member would pay not only for medical attendance but also for medicines, it is clear that

phthical patients might gain admission in such numbers that supplying them with cod-liver oil and expensive drugs might rapidly absorb the sundry farthings that had found a temporary resting-place in the medical men's pockets. These are brilliant prospects for the future of the medical profession. On those difficulties being pointed out to the agent, he said that he personally would obviate the whole of them. He would not accept any members except those having small incomes, he would limit distances according to the wishes of the medical officers, and if any chronic cases chanced to find their way into the society he would pay them back their money and get rid of them. What if his successor did not prove equally complaisant? Oh! he himself intended settling down for the remainder of his life in Cork; though he had previously mentioned that he had "opened up" Kent, Sussex, and the Channel Islands. Could he not have inserted in the rules of his society the promises he had referred to? No. Why? Because printing new rules would cost too much! He has already engaged the services of eighteen canvassers, and he will be surprised if the Cork medical men will not avail themselves of such a favourable opportunity. But the latter had their own views of the whole project, and at a specially convened meeting of the profession, apart from all other considerations, they denounced the touting and canvassing so inseparable from the system as calculated to prostitute the practice of medicine and bedaub the escutcheon of an honourable profession.

Curious Action against a Medical Practitioner.

A case, which has created considerable interest, has just terminated, after a hearing of three days, in a verdict for the plaintiff, with damages £100. The decision is of great importance to the medical profession, for it clearly demonstrates the reality of the dangers which medical men are so frequently obliged to face in carrying out their duty to the public, more especially in connexion with the notification of infectious disease. The action was brought by Mr. Andrew Mason, a draper carrying on business in Rathmines, against Dr. John E. Hadden, of the same suburb, to recover damages for having "negligently, improperly, and unskillfully diagnosed as small-pox" a disease which was not small-pox, but erythema nodosum; for having the patient, a young girl named Maria Hawkins, in the plaintiff's employment, removed to Cork-street Hospital; and for having, under the Infectious Diseases (Notification) Act, reported the case to the municipal authorities of Rathmines as a case of small-pox, to the injury of the plaintiff's business. The facts, as reported in the daily journals, are briefly as follows. On the evening of Dec. 10th the defendant was summoned to see the girl Maria Hawkins, whom he found in a room in Mr. Mason's establishment, said to be occupied at night by her and seven other employés. The patient's temperature was 103° F., and she complained of pains in the back, &c., while numerous raised spots of erythema were visible on her forehead as well as on her limbs. Dr. Hadden, who had revaccinated this girl some weeks before, made a diagnosis of modified small-pox, a disease then very prevalent in Rathmines, and directed that she should be removed to hospital. He, moreover, notified the municipal authorities of the existence of a case of small-pox at Mr. Mason's establishment. Next morning the patient was brought to Cork-street Hospital and admitted by the resident medical officer, who stated, however, that she was suffering from erythema nodosum, and not from small-pox. Mr. Mason, hearing this, accused Dr. Hadden of having made a mistake in his diagnosis in his notification under the Infectious Diseases Act, &c., as stated above. The defendant denied the negligence; denied that he had improperly or unskillfully diagnosed the disease; denied that the plaintiff had suffered any of the loss or damage alleged; denied the writing of the letter to the town commissioners; that the words in the letter were not written or published in the defamatory sense imputed, nor in any defamatory sense. There was a special defence to the effect that the words "were written and published by the defendant honestly believing that the said Maria Hawkins was then suffering from small-pox, for the purpose of complying with the terms of the Infectious Diseases (Notification) Acts, 1889 and 1890, whereby the defendant was bound under penalty, on becoming aware that any patient of his was suffering from an infectious disease, to notify the same to the medical officer of health for the district, and not otherwise, and the persons to whom the said words were published had a legitimate interest in being informed thereof for the purposes of the said Acts, and the

said words were published by the defendant on a privileged occasion for the purpose aforesaid *bonâ fide* and without malice, and in the belief that they were true." There was really no suggestion that Dr. Hadden's action in the whole matter had been anything but *bonâ fide* and dictated by the highest sense of public duty. Mr. Wright, Q.C., his counsel, admitted, however, that he had been "guilty of an error in judgment," but the subsequent evidence of experts threw considerable doubt on the propriety of even this admission. Dr. Thornley Stoker, the President of the Royal College of Surgeons in Ireland, stated that, placed in Dr. Hadden's position, "he would have done exactly as he did"; and in cross-examination said that he "was of opinion that the case really was one of small-pox." In this view Dr. J. W. Moore, an acknowledged authority on the subject of fevers, concurred. Dr. James Little, a physician of the highest position and of very large experience, stated in his evidence that "the symptoms described in court would certainly lead to the belief that the case was one of small-pox." The patient was detained in hospital for more than a month, but she has long since perfectly recovered. If the disease was small-pox, it has never reappeared at Mr. Mason's establishment, a fact owing perhaps to the unselfish public spirit of Dr. Hadden, for the exhibition of which he is now about to pay £100. Dr. Hadden, who is a Bachelor of Medicine and Surgery of Dublin University, is well known, and much sympathy is felt for him.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Sulphonal and Urine Analysis.

M. LAFON¹ had under treatment a patient who, in 1891, passed 183 grammes of sugar daily in his urine. In a few months all trace of glucose disappeared. For the last two months an average daily dose of 75 centigrammes to 1 gramme of sulphonal has been taken. A somewhat prolonged boiling of the urine with Fehling's solution invariably determines a characteristic reduction, although the polarisaccharometer reveals, not a deviation to the right, but slightly to the left. That the reducing properties conferred on the urine by the ingestion of sulphonal are not caused by any transformation of that drug in the system is proved by the fact that the addition of a medicinal dose (1 gramme per litre) to urine quite free from sugar confers the same reducing power. The practitioner would thus do well to think of the sulphonal habit before he comes to the conclusion that the success of the copper test in any given case is indicative of the presence of glucose.

Anosmia cured by Douches of Carbonic Acid Gas.

Dr. Joal of Mont-Dore² had recently under his care two cases of this obstinate disease. In both instances all sense of smell and taste had disappeared for several months past and had been unsuccessfully treated by irrigation, the galvano-cautery, electricity, and insufflations with a powder containing strychnine. The two lost senses were completely restored by the employment of douches of CO₂ gas. The *modus operandi* is most simple. An ordinary seltzer syphon is turned upside down, the excess of liquid is allowed to escape through the tap, and the orifice is then held close to the nostrils. Dr. Joal recommends the same remedy at the commencement and during the course of common colds.

Formyl Aldehyde as a Disinfecting Agent.

In the February number of the *Revue d'Hygiène* I find a suggestive paper by MM. Gambier and Brochet on the utility of the above product in the disinfection of rooms. It is stated that formyl aldehyde is capable of radically sterilising all dust germs as also the anthrax bacillus and its spores, and this even when employed in minute doses, provided always that the room be hermetically sealed and that the duration of the process be sufficiently prolonged. Moulds possess more resisting power than bacteria; amongst these latter those which favour putrefaction are the soonest destroyed. The most resisting micro-organism is the inoffensive bacillus subtilis. Experiments conducted in a room of 75 cubic metres were less conclusive than those made in the laboratory. It must not be forgotten, however, that the temperature was low and that a good deal of

¹ Académie des Sciences, April 29th.

² Société Française de Laryngologie et d'Otologie, May 4th.

leakage of the gas was inevitable through numerous apertures impossible to close. Nevertheless, even under these unfavourable conditions, a relatively small quantity of aldehyde gas brought about the destruction of nearly all the dust germs deposited in the room. An increase in the volume of the gas used did not appear to produce appreciably better results. As above stated, the resisting germ was invariably the bacillus subtilis of hay. The penetrating properties of the gas are shown by the fact that dust placed to the depth of one centimetre in beakers, themselves placed on shelves in a cupboard, was found, after an exposure of twenty hours to the aldehyde vapour, to be completely sterilised. It would then appear that the employment of this valuable disinfecting agent is specially indicated in the case of breakable or precious objects, and also in the case of rooms which are not too large. Its great advantage over the sublimate spray is that the objects to be purified need not be displaced, unless it be bedding, carpets, and curtains, which are better disinfected in an oven. It has been noticed that any germs that have escaped destruction at a first operation are destroyed at a second. Formal-aldehyde lamps are employed for the generation of the gas.

The New Military Medical School of Lyons.

This establishment was, with much pomp and ceremony, formally opened on the 12th inst. by General Zurlinden, Minister of War, who was accompanied by Dr. Dujardin-Beaumetz, *médecin inspecteur général*, Dr. Gaillon, the Mayor of Lyons, and a brilliant staff. Quite a large force of troops of nearly all arms marched past the Minister when he had taken his station on the steps in front of the school buildings. The actual ceremony of inauguration took place in the vast courtyard of the school, where all the students, headed by their professors, were massed. Speeches were delivered by Dr. Gaillon and the Minister, feeling allusions being made to such past ornaments of the army medical service as Percy, Larrey, Desgenettes, Sédillot, Villemin, and others. This ceremony should have taken place in July last, but the sad tragedy involving the death of President Carnot necessitated its postponement. Dr. Gaillon has, by the way, been created Grand Officer of the Legion of Honour.

May 14th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Prophylactic Measures against Tuberculosis.

At a recent meeting of the Berlin Medical Society Professor Cornet read a paper on the above subject. He had already suggested that the tubercle bacillus is not ubiquitous, as some observers suppose, and is present only where phthisical patients have expectorated and where the dried sputum has afterwards become dispersed. This result he had arrived at by very extensive examinations of the wards in hospitals, and the rooms in barracks, prisons, and monasteries, where crowds of people live together in a limited space; the dust and mud of the streets were also carefully examined by him. In rooms where spittoons containing some water were in use he very seldom found the bacillus even if phthisical patients lived there. According to him the prophylactic measures are very simple: a large number of spittoons partially filled with water should be provided in order to prevent people from spitting on the floors, and handkerchiefs should not be used for receiving expectoration; moreover, the floors of houses and the streets ought to be sprinkled with water as often as possible. Heredity had less influence on the origin of tuberculosis than was generally believed. In a great many cases where the children of phthisical parents were attacked with the disease, the communication might be due, not to heredity, but to mere contagion. The number of those suffering from phthisis is, in Professor Cornet's opinion, estimated to be higher than the results of necropsies warrant. It is an error to suppose that the atmosphere is filled with tubercle bacilli; they are dangerous only where the necessary precautions are neglected. In proof of the efficacy of hygiene in reducing the dangers of tuberculosis Professor Cornet mentioned that on his advice the Government had taken the above-described measures to prevent the general dispersion of sputum in prisons and lunatic asylums, and that since this time the mortality

from phthisis in these institutions had obviously decreased. The new regulations came into force in 1889. In the prisons the deaths from phthisis per 10,000 inmates were 146.7 during the period 1884-86, 144.5 in 1886-88, 101 in 1888-90, 89.4 in 1890-92, and only 81.2 in 1892-94. In the lunatic asylums the corresponding phthisis death-rate was 198 in 1886, 180 in 1887, 184 in 1888, 155 in 1889, 152 in 1890, and 156 in 1891. The mortality had also decreased in those convents whose superiors had followed Professor Cornet's recommendations. These statistics show that cleanliness and intelligent care are the best means of preventing the propagation of tuberculosis. In the course of the ensuing discussion Professor Virchow said that it would be a great advantage if persons would refrain from expectorating in public places, but according to his experience there was little inclination to follow hygienic prescriptions. In the university he had often seen students who had received a hygienic education neglecting the spittoons and expectorating anywhere. Dried sputum was often to be seen in railway carriages, a circumstance which would of course be extremely conducive to the propagation of tuberculosis among travellers. Railway authorities ought to give especial attention to those carriages which convey invalids to health resorts. Commenting on the statistics quoted by Professor Cornet, he said that he was not yet entirely persuaded that the decreased mortality in prisons and asylums was really an effect of the hygienic measures taken by the Government. Dr. Baer, medical officer to the great penitentiary of Plötzensee, near Berlin, said that simultaneously with the prophylactic regulations of the Government the dietary of the prisoners was improved and the overcrowding of the buildings was discontinued. These circumstances, he thought, were of no small importance in the prevention of tuberculosis.

The Etiology of Blackwater Fever.

Dr. Plehn, medical officer to the colonial Government of Cameroon (West Coast of Africa), has made valuable researches on the above disease, which is scientifically known as paroxysmal hæmoglobinuria. In a communication to the Berlin Medical Society he states that Europeans and Chinese are particularly subject to this complaint, negroes, some cases excepted, being exempt. Robust persons, both men and women, are especially liable to be attacked. The duration of the incubation is very uncertain. Blackwater fever nearly always follows typical malaria; Dr. Plehn has seen only three cases of the disease without antecedent malaria. The disease is apt to break out after hard work or mental excitement. Microscopically he had observed a diminution of the red blood-corpuscles; the leucocytes often assume the form of macrocytes, but seldom that of poikilocytes. By means of staining methods he had recognised in the blood plasmodia similar to those of malaria, but with a less affinity for aniline colours. He believes that both the plasmodia of malaria and blackwater fever are varieties of the same species. Drugs are unnecessary, the disease having a tendency to spontaneous recovery.

Death of Professor Nüggerath.

Professor Nüggerath, the well-known gynaecologist, died in Wiesbaden on May 5th. Although a German by birth, he spent the greater part of his life in America. Born in Bonn in 1807 he became assistant at the Hospital for Women in his native town, and in 1856 he was called to New York, where he became Professor of Gynaecology in the Medical College. He made valuable researches on the Etiology of Endometritis, Leucorrhœa, and the Inflammatory Diseases of the Sexual Organs. In 1889 he left New York for Wiesbaden, where he resided till his death. His last work, entitled "Contributions to the Structure and Origin of Carcinoma," appeared in 1892.

May 14th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Balnæary Hygiene.

THE modern Roman laments, and not without reason, the absence of those means of personal ablution which were open to all, from the patrician to the mechanic, under the Empire, and even the Republic before it. In the baths of Caracalla, for example, and, later still, in those of Diocletian, the humblest no less than the highest citizen could cleanse and

reinvigorate his body by an admirably organised series of balneary arrangements, to some extent perpetuated in the so-called "Turkish" (which is really the Roman) bath of the present day. During the summer heat, now imminent, Rome is absolutely without such a resource on a popular scale, and, as usual, has the mortification of seeing the more enterprising cities of the Alta Italia exelling her in this desirable direction. At Turin there were opened on the 4th inst. for public use a splendid array of baths, each in a separate chamber, the price charged being not more than 15 centimes (1½d.) apiece, service and linen included. The water is maintained at a constant temperature of 30° to 32° C., which, if specially required, can be lowered or heightened without loss of time. The establishment has a female wing as well as a male, and the service is scrupulously regulated to suit the convenience of both sexes. The baths are open every day from 5 A.M. to 8 P.M., and on holidays from 5 A.M. to 6 P.M. Rome, I am sure, would consult her own interests by a return to the bathing system of which her ruined aqueducts are the still magnificent monuments. For one thing, she would have a much better chance of attracting the tourist in the summer months if he could count on keeping himself cool and comfortable by such a resource as that now open to him in Turin.

The Italian Red Cross.

There may or may not be "gunpowder in the air," and nearer home than the Tropics, but one thing is certain, that throughout Europe there is an extraordinary activity in all the Red Cross organisations. Italy, as becomes the nationality which justly claims priority in the humanitarian conception which had its culmination in the Geneva Convention under General Dufour in 1869, is very much *en évidence* in this direction. Not only has she equipped and sent out to the Tigré a first relay of what promises to be a singularly complete Red Cross service, but she is making energetic preparations for the autumn manoeuvres, which are to come off this year in the central provinces. As in those of 1894 she broke fresh ground, particularly in the railway and mountain transport service, so in 1895 she has in store some "surprises" equally interesting, and perhaps worthy of imitation in other departments. On the 4th inst. there was held here a general meeting of the "Croce Rossa Italiana" to consider certain important questions of uniform, of promotion, of the reciprocity of salutation with the combatant force, and other details affecting the more efficient organisation of the service. These, after due discussion, were put in the concrete form of resolutions to be submitted at the proper time to headquarters.

May 6th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Athletics and Casualties.

THE Committee on Hygiene and Athletics of the Board of Visitors to the Military Academy at West Point have compiled the following statement of the casualties from the hospital records for two periods of three months each—viz.: football injuries, 91; injuries in riding-hall, 45; injuries in gymnasium, 19. But this is by no means a fair comparison, for there were but 61 football players, while those under instruction in the riding-hall numbered 382, and those in the gymnasium 207. Furthermore, football was played but once a week, while the riding exercises took place three times a week, and those in the gymnasium six times. Finally, the football injuries were, as a rule, more severe than those sustained in the riding-hall or gymnasium. This is the first contribution of accurate comparative data with regard to these three forms of athletics in the same institution under identical surroundings and by the same class of men. If the frequency of gymnastics (six times a week), of riding (three times a week), and of football (once a week) are taken into account, it shows that per man playing there were respectively from about 20 to 100 times as many accidents in football as in the riding-hall and gymnasium, and that the gravity of the accidents, as measured by the number of days lost per man playing, or per man injured, or by the number of men off duty per diem, is vastly greater in the case of football than of either of the other two forms of athletics.

The Bicycle for Medical Men.

An animated discussion occurred in a medical society of New York on the question as to the effects of bicycle riding

on persons suffering from various diseases. Though there was some difference of opinion the general sentiment was very favourable to the use of the bicycle. Perhaps the most interesting feature of the discussion was the admission of many physicians that riding the bicycle was their favourite method of exercise. A physician of Louisville who has abandoned his carriage and adopted the bicycle in his visits to his patients, after describing the improvement of his own health by the change, states that he recommends it for phthisical patients well progressed in the disease, as by its gentle and prudent use their appetites were increased, their digestive and assimilative powers enhanced, and their sleep prolonged and made more refreshing. He deprecates too rapid riding, approves the upright position, and enjoins frequent intervals of rest. He has been consulted by many who think they have been injured by the bicycle, but he has always found their troubles due to a faulty adjustment of the saddle or to the riding having been too long and wearisome.

Condemnation of Insanitary Buildings.

No new provision of a recent Act of the Legislature of New York is more valuable than that providing for the condemnation of insanitary buildings, especially those which injure the sanitary condition of a neighbourhood. The initiative must be taken by the Board of Health and the proceedings carried on through the courts, with compensation so moderate that the law will not be a premium upon neglect on the part of landlords. It is mathematically proved in the report to the Legislature of the Tenement House Committee that there are houses in New York which breed and disseminate the germs of disease, and are a menace not only to their inhabitants but to the whole community. The introduction of small parks should do away with some of these, and well considered condemnation proceedings can destroy others. There is no doubt that the legislation which will most favourably affect the death-rate of New York is such as will do away with the rear tenements, and root out every old, ramshackle, disease-breeding tenement house in this city.

Antiseptic Operating Theatres.

There is a gratifying interest now taken by wealthy citizens in securing to hospitals a separate building for operations where needful antiseptic appliances may be made. The most notable instance is the Syms' Operating Theatre of Roosevelt Hospital in this city, built at an expense of 40,000 dollars. Every arrangement possible for successful antiseptics is here provided. At Worcester and Pittsfield, Mass., at Chicago, and in many other localities similar buildings are being erected on endowments by citizens. The results are that these hospitals are attracting surgical patients from distant places, and even from hospitals which have no such provision.

Destruction of Tenement Houses by Fire.

During the past few years the number of tenement houses destroyed by fire in New York, and the consequent loss of life as well as property, has excited public alarm. The Committee on Tenement Houses, to which allusion has been made, state that it is a startling fact that, whereas the tenements of New York are only 31 per cent. of all the buildings, 53 per cent. of the fires occur in tenement houses. The greatest activity of the fire department is in the tenement house districts. Whatever the sociological reason of the frequency of these fires, it is a fact that the danger from fire is an ever-present menace to the tenement house population. The loss and misery from these perils cannot well be exaggerated. It is not merely a death danger, but a mental terror, and a threatened loss of property falling upon those who can so easily lose all they possess. The cost of fire protection by means of the fire department is twice that of the large city of London, and in proportion to population four times that of London. The whole city is taxed to meet the expense of fire precautions in our tenement houses. The committee thought that its duty would not be performed without providing additional safeguards as to fire in connexion with dangerous occupations or uses in existing tenements. In response to the request of the committee laws have recently been passed requiring that tenement buildings shall be made fireproof.

April 27th.

THE CASE OF DR. CORNELIUS HERZ.—We have received from Mr. Malcolm McHardy a series of important certificates and a letter to the Home Secretary concerning Dr. Cornelius Herz. Unfortunately they were received too late for publication this week.

Obituary.

HARRIS BUTTERFIELD, M.R.C.S. ENG., L.S.A.

THE announcement made in THE LANCET of May 4th that Mr. Harris Butterfield had expired at his residence in the Granville-road, Sevenoaks, Kent, was received with universal expressions of regret throughout the district. It is some twelve years since Mr. Butterfield was appointed medical officer of health for West Kent in succession to Dr. O. Bayliss, and he won and maintained the respect and esteem of all with whom his important and responsible duties brought him in contact. He was an honorary member (late President) of the Bradford Medico-Chirurgical Society, Fellow of the Society of Medical Officers of Health, Member of the Epidemiological Society, and formerly surgeon to the Southampton Dispensary and Beaufort Ironworks. The deceased gentleman had been ailing for a considerable time. Some few months ago he underwent a painful operation for cancer, it was then hoped successfully, but the insidious disease speedily reasserted itself, and although his medical attendant, Mr. Blomfield, was unremitting in his attendance his skill was unavailing. Mr. Butterfield was fifty-nine years of age, and leaves a widow, two sons, and a married daughter to mourn their loss. The funeral took place at the Sevenoaks Cemetery. The body of the deceased was placed in a plain oak coffin with brass mountings, the name-plate bearing the inscription: "Harris Butterfield, born June 7th, 1835, died May 1st, 1895." A large number of friends of the deceased followed the coffin to the grave. The first portion of the service was conducted by the Rev. R. A. Mitchell, curate of St. Mary-at-the-Walls, Colchester, and the concluding sentences at the graveside were read by the Rev. Thomas Stevens, chaplain to the Sevenoaks Union.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following gentlemen passed the First Professional Examination for the Diploma of Fellow at a meeting of Examiners on Monday, the 13th inst. :—

Bennett, William Edward, L.R.C.P. Lond., M.R.C.S. Eng., Mason College, Birmingham, and St. Bartholomew's Hospital.
Burgess, Arthur Henry, Owens College, Manchester.
Campbell, Robert, M.B., R.U. Ire., L.R.C.P. Lond., M.R.C.S. Eng., Queen's College, Belfast.
Dick, John Lawson, M.B. Edin., L.R.C.P. Lond., M.R.C.S. Eng., Edinburgh University and St. Bartholomew's Hospital.
Wood, William Bird Heraparth, Mason College, Birmingham.

Fifteen gentlemen were referred back to their professional studies for six months.

Passed on Tuesday, the 14th inst. :—

Atkinson, Arthur Edward, L.R.C.P. Lond., M.R.C.S. Eng., Mid-
dlesex and St. Thomas's Hospitals.
Buttye, Walter Rodney, University Colleges Bristol and London.
Davies, David Lawford Francis, Middlesex Hospital.
Molesworth, Theodore Henderson, Cambridge University and St.
Bartholomew's Hospital.

Fifteen gentlemen were referred back to their professional studies for six months.

The following are the arrangements for the Final Examination for the Fellowship, for which forty-seven candidates have entered their names:—At the Examination Hall: Monday, 20th, Written Examination, 1.30 to 5.30 P.M.; Tuesday, 21st, Clinical Examination, 2.30 to about 6.30 P.M.; Wednesday, 22nd, Operations, 1.30 to about 6 P.M.; Thursday, 23rd, Surgical Anatomy, 2 to about 4.15 P.M. At the Royal College of Surgeons: Friday, 24th, and Saturday, 25th, Pathology, 5 to about 8 P.M. Candidates will be required to attend on each of the first four days and on the Friday or the Saturday.

ST. GEORGE'S HOSPITAL GRAPHIC SOCIETY.—

The general meeting of the St. George's Hospital Graphic Society will be held on Tuesday, May 28th, at 2.30 P.M. By permission of the Board of Governors the annual exhibition, which is strictly limited to the work of the members, will be held in the museum of the Hospital. The exhibition will be opened immediately after the meeting, and will remain open until the end of the week. Visitors will be admitted on presentation of their visiting cards.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a meeting of the College on the 9th inst., Sir J. Russell Reynolds, President, in the chair, the newly elected Fellows were admitted. An application from the Pathological Museum Committee of the British Medical Association for the loan of specimens from the College Museum was granted. A lengthy and elaborate report from the Pharmacopœia Committee recommending numerous omissions from the present Pharmacopœia, as well as additions to the forthcoming volume, and suggestions on other details, was presented by Sir A. Garrod, chairman of the committee. A discussion followed, shared in by Dr. Farquharson, Dr. Burney Yeo, Dr. Squire, Dr. C. T. Williams, Dr. Hare, Sir Dyce Duckworth, Dr. D. Leech, and Dr. Norman Moore; and eventually, on the motion of Sir R. Quain, seconded by the Senior Censor, it was resolved to transmit the report to the General Medical Council. A proposal by the treasurer that the Harveian dinner be not held this year was agreed to. Reports were received from the University Committee and the Committee of Management.

UNIVERSITY OF LONDON: MEETING OF CONVOCATION.—

At the ordinary meeting of Convocation on the 14th inst. Mr. E. H. Busk, M.A., LL.B., was re-elected to the office of chairman and Mr. H. E. Allen, LL.B., B.A., to that of clerk. The report of the annual committee was presented by Professor Silvanus Thompson, and adopted. Mr. H. M. Bompas, Q.C., moved: "That the three resolutions contained in Paragraphs 7, 10, and 12 of the minutes of Convocation held on Jan. 22nd, 1895, are hereby rescinded, this house being of opinion that if a local teaching university for London be desirable it ought to be constituted apart from the existing University of London." He said that the particular question which he desired to raise had not been put to the University fairly and straightly before. It was proposed that there should be only one university, and that that university should preserve an equality between the colleges of London and the country. It seemed to him that that was equivalent to saying that it was desirable to have twice two, if twice two were five. He thought it was an absolute physical and intellectual impossibility to carry the proposal into effect. He was of opinion that if there was to be a teaching university it should be separate from the existing University. If there was to be a teaching university—a university of which the examinations were mainly controlled by the professors and teachers, and where the attendance at lectures should count instead of mere examinations as a means of getting a degree—such university should be separate from the present University. It was because every man, whether he came from the colleges or whether he taught himself, whether he was examined in London or in Calcutta, felt that there was a fair standard to which he was subjected, that they had been able to draw men from all the other universities and all the other colleges, because they could get from them something which they could get nowhere else in the world. That was the great work which the London University had done, and the great value of its degrees. The Gresham scheme proposed to entirely alter that, and if it were carried out the effect would be to establish an examination of such a character that those trained in the London colleges would have an advantage over those trained elsewhere. He was agreed that there should be a teaching university for London, but it should stand on its own merits and be separate from the present University. Mr. Cozens-Hardy opposed the resolution. He said that if he thought the scheme would put an end to non-collegiate students he would have nothing to do with it. It was because he thought it was vital to the interests of non-collegiate students that they should be in association with a university of the highest reputation that he opposed Mr. Bompas's proposal. Dr. Heber Hart supported the resolution, and a long debate followed. In which Dr. Fitch, Mr. J. E. H. Cotton, Mr. T. C. Lowe, Mr. Thomas, Mr. Hanford, Dr. Snow, and Principal Cave took part. Eventually the motion was put to the meeting, and on a show of hands being taken the chairman declared it to be lost. On a division it was found that 117 voted in favour of the motion and 238 against it. The chairman then announced that out of the list of three persons nominated to be submitted to Her Majesty for the selection therefrom of a Fellow of the University Mr. Thomas Bateman Napier, LL.D., had received 1231 votes, and Mr. Cozens-Hardy 733 votes.

ST. MARY'S HOSPITAL, LONDON, W.—At the opening by Her Royal Highness the Princess of Wales of the grand bazaar in aid of St. Mary's Hospital at Portman Rooms on June 27th next, the Princess of Wales will be received on her arrival at the bazaar by their Royal Highnesses the Duke and Duchess of York.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Tuberculosis Commission.

NOTICE has been given by Mr. Knowles of the following motion in connexion with the report of the Royal Commission on Tuberculosis, viz.: "That the Commission be reappointed and the scope of its inquiry extended, so that it may further inquire and report on administrative procedures available for reducing the amount of tuberculous material in the food supplied by animals to man."

Factories and Workshops Bill.

Steady and substantial progress is being made with this Bill by the Grand Committee on Trade. On Tuesday of this week there was a good deal of discussion with reference to Clause 6, which imposes a penalty not exceeding £20 for knowingly allowing wearing apparel to be made in a place where any inmate is suffering from scarlet fever or small-pox. Sir Charles Dilke moved an amendment to strike out the word "knowingly," and insert words placing on the occupier the onus of proving that he was not aware of the existence of the illness in the building, and could not reasonably have been expected to become aware of it. Several members thought the amendment impracticable, but eventually it was agreed to. A long discussion took place on an amendment freeing from liability persons who gave out work to places where the illness broke out after the work had been received. Mr. Asquith met it by promising to see whether a subsection could be drawn up requiring anyone who received work back from an infected place to have the work disinfected before letting it go to the purchaser. Later Dr. Farquharson moved to leave out "scarlet fever and small-pox," and substitute "any of the diseases specified in Section 6 of the Infectious Diseases (Notification) Act, 1893." He had, he said, consulted some of the best medical authorities, and they agreed that the limitation to two diseases was too narrow. Mr. Asquith, however, objected to the amendment on the ground that it would widen the scope of the clause beyond anything that was reasonable. Sir John Gorst put forward a claim to have diphtheria included. Without pledging himself to alter the clause Mr. Asquith undertook to consult the medical officers of the Local Government Board on the point.

HOUSE OF LORDS.

THURSDAY, MAY 9TH.

London University Bill.

Lord Playfair presented a Bill for the purpose of reconstituting the London University. He explained that in 1892 the late Government appointed a Royal Commission to consider whether the London University might be converted into a teaching university, or whether it was necessary to form a new university for London. The Commission, having regard to the position and experience of the London University, came to the conclusion that it would be better to reconstitute it than establish a new university, and accordingly they issued a scheme which was very favourably received by all the interests concerned. The Commission pointed out that it would be exceedingly difficult to carry out the scheme by a charter, and recommended legislative authority—that was to say, the appointment of a Statutory Commission. The plan of giving such powers to a Statutory Commission was a very old one, having been applied to Oxford and Cambridge and the Scottish universities when there were fundamental changes to be made. There was no intention by this Bill to interfere with the present imperial character of London University, which, indeed, was specially preserved by a clause.—The Bill was read a first time.

TUESDAY, MAY 14TH.

Midwives Registration Bill.

SECOND READING DEBATE.

The second reading stage of the Midwives Registration Bill, the text of which we published last week, was taken in the House of Lords on Tuesday, May 14th.

Lord Balfour of Burleigh, in making the motion for the second reading, said he had had two interviews with the present President of the General Medical Council, and he had also had the advantage of the advice and counsel of many personal friends well entitled to form an opinion on the subject of midwifery. All the information he had been able to get led him to the conclusion that a case for this measure, or something like it, could be presented which, so far as its outlines were concerned, must carry conviction to every unbiased mind. Any one who studied the returns of the Registrar-General would see there were every year in this country between 800,000 and 900,000 births. More than half of those births were attended by midwives only; and it was, he thought, universally acknowledged that the great majority of the midwives were almost wholly, if not wholly, untrained and in many cases lamentably ignorant of the important duties they undertook to discharge. In this country alone amongst European countries was no care or supervision exercised over the calling of the midwife. It was

actually the fact that in England at the present time, no conduct, however improper or disgraceful, would prevent any woman from undertaking and continuing the calling of a midwife; the fact that a woman who had undertaken it had actually been convicted upon a criminal charge would not justify any authority in intervening and preventing her continuing to practise. The state of matters consequent upon this was by competent medical authorities proclaimed to be that the mortality amongst mothers of those classes who chiefly employed these women was much greater than it ought to be and much greater than it might be brought to be. Disease, too, in both mothers and children was also found to result from incompetent attendance during childbirth. The General Medical Council urged upon the Government the importance of passing into law some measure for the education and registration of midwives, and THE LANCET and the *British Medical Journal* had written of the ill-effects resulting from the ignorance and incompetence displayed by many midwives. In spite of the report of the Select Committee of the House of Commons which sat in 1892-93 nothing had been done. That report made it clear that midwives, without the supervision of qualified medical men, did attend women of the humbler classes in great numbers; that a great number of them were untrained, and, therefore, unfitted for their important duties; and that the mortality and injuries resulting from want of skill in the midwife were greater than they ought to be. He had received the following letter on the subject from Sir John Williams, whose opinions would be received with the respect due to so high an authority:—

"DEAR LORD BALFOUR.—In common with a very large number of medical men, I am grateful to you for introducing into the House of Lords a Bill for the Registration of Midwives. The large number of births attended by midwives alone, and the frequency of serious and even fatal results arising from ignorance on the part of midwives of the process of natural labour, make it most desirable that the poorer women of the country who are unable to obtain the services of a medical man should be able to secure the help of a midwife who has an elementary knowledge of midwifery. The mortality after childbirth is considerably greater than is generally supposed. This mortality is due to two classes of cases, one being preventable and the other not preventable. That due to preventable causes forms the larger section, and amounts to two-thirds or three-fourths of the whole. The preventable causes consist of infection and some forms of abnormal development and departure from the natural mechanism, and upon a knowledge of the means for preventing infection and an ability to distinguish abnormality at an early period depends success in preventing or reducing mortality. It cannot be doubted that the mortality of children among the poorer classes would be greatly reduced if the women attending them possessed the elementary knowledge to which I have referred.—I am, my lord, yours truly,"

"JOHN WILLIAMS."

On a high authority there was all this preventable loss which might fall most tragically on the homes of the poor. The proposals of the Bill, which formed a well-considered measure of reform, were short and simple. The Bill provided for the registration of midwives, and prohibited those who were not registered from using the title; but it did not do what was impossible, and prohibit them from practising. Common humanity permitted anyone to go to the assistance of a fellow-creature in pain or misery. The proposal of the Bill followed the precedent of former legislation in regard to doctors, dentists, veterinary surgeons, and chemists and druggists. Then the Bill formed a board which would keep the register and admit midwives to registration after proper examination, framing rules for their guidance and control. In all these matters the board was to be subject to the regulation and control of the General Medical Council, and the original draft of the Bill had been altered in accordance with the wishes of the President of the General Medical Council. Then certain privileges were given to registered midwives, such as the right to use the title of midwife and the right to recover fees by law. The specialists on the diseases of women, who had been consulted, approved of the form of the Bill, but some objections had been urged by others—notably, that the Bill set up a new class of medical practitioners. This was not the case. It simply provided that practising midwives should be so far educated as to be able to recognise the limits of what they might attempt, and to know when a medical man ought to be called in. These women could not be prevented from practising, and it was better that the people whom they attended should have the power to discriminate between those with qualifications and those without. The work of supervision and education could only be properly done by the sanction of law. He could fortify himself by an authority which he thought their lordships would accept. Two years ago, after the report of the Select Committee was issued, THE LANCET had a leading article on the subject. It cast a great deal of ridicule on those who took this objection. THE LANCET said: "We have not much sympathy with the remark that it is impossible to define 'natural labour.' We live in a practical world, and it is not impossible to lay down rules of conduct intelligible to women of any training that will enable them to know when to send for medical assistance and enable those who supervise them to know when they have been culpable in not so sending." There was one objection which had not been raised and to which he referred for fear of misconception. It had not been actually suggested, but it was impossible to remain blind to the fact that it had been hinted that one effect of the Bill would be to take away business from medical men. He did not believe that any large section of the medical profession would raise such an objection, but if it were raised he did not think that Parliament would listen to it for a moment. So far, however, from the Bill having this effect, he believed that the effect of such legislation would be to teach women when to send for medical advice. This was no question of party conflict; it was one of domestic reform of the greatest importance to a large class little able to help themselves. Some measure of this kind, moreover, was one of clamant necessity in the interests of public health as well as in the interests of common humanity.

Lord Thring, while agreeing with the necessity for educating midwives, asked that justice should be done to the 8000 or 10,000 women at present engaged in the profession. Under the Bill women would not be able to obtain any education at all, because it almost placed education out of their reach, while there were no lady doctors or laymen on the council. It was a strictly professional council who had to make regulations for the midwives. The recommendation of the Select Committee that there should be local examinations and that the local infirmary or hospital should be utilised for educating midwives was not

followed in the Bill. Neither was the recommendation that the county councils should have a controlling power over these women. The question was a local one, whereas this Bill embodied a centralised system of education in London of the most extensive character quite unattainable by poor women. He hoped the Bill would be referred to a Select Committee and due care taken to see that midwives were properly represented on the council.

Lord Playfair, speaking on behalf of the Government, said that they had no objection to the general principle involved in the Bill, though they considered that several important amendments might be necessary. There was certainly an immense amount of ignorance among midwives, and there was a great deal of preventable illness which would not occur if more competent midwives were engaged. One point of weakness in the Bill was the attempt to define "natural labour" which midwives, qualified or not, might attend. It was an extremely difficult point to define; but out of 15,000 cases analysed 983 in 1000 were cases of natural labour, and only the balance were obliged to send for medical men. The Bill provided that no one should call herself midwife alone or with an adjective unless she had been examined, certified, and registered under this Bill. But "midwife" was one of the oldest Saxon words in the English language, and it would be very difficult in a Bill to acquire a monopoly of it for a special purpose or a special class of persons. He drew attention to Clauses 3 to 12, because he feared that they enjoined so much and were so elaborate that in practice they would defeat the Bill and prevent its success. The fee of two guineas for examination and registration was already very high for persons of this class. More money would be obtained if the fee was lower and if the examinations were local as well as central. He assured the noble lord that personally, as well as officially representing the Privy Council, he had much sympathy with the Bill; but he would ask the noble lord to postpone its further consideration for a little while so as to enable the Government to consider what amendments they should put down before the committee stage.—Lord Balfour of Burleigh undertook to confer with the Privy Council and also with representatives of the Government and other members of their lordship's House before putting down the Bill for the committee stage.—The Bill was then read a second time.

HOUSE OF COMMONS.

THURSDAY, MAY 9TH.

The Question of the Unemployed.

Mr. Campbell Bannerman, Chairman of the Select Committee on Distress arising from Want of Employment, said, in reply to a question, that the Committee were engaged upon a large and difficult task, and in his opinion they would not be doing their duty if they offered advice to the House without adequate information as to the facts and as to the principal remedies that had been proposed. They were, therefore, busily engaged in obtaining such information from the most promising sources; but he trusted that this necessary process would not occupy more than a few weeks longer, and that the Committee would be able then to submit a report. They are most anxious on every ground to avoid unnecessary delay.

Imported Milk.

Mr. Shaw-Lefevre said, in reply to a question, that he was not aware that there was any evidence that disease had been spread in this country by imported milk. With insignificant exceptions, imported milk was in a condensed form, and the processes of heat to which it was subjected, he was advised, destroyed its powers to convey infection, whether of foot and mouth disease or tuberculosis. The Local Government Board had no power to prohibit the importation of foreign milk.

FRIDAY, MAY 10TH.

The Army Meat-supply.

Mr. Field asked the Secretary of State for War whether it was a fact that in Ireland, a meat-exporting country, the troops were mainly rationed upon foreign meat; whether he could state the percentage of native and foreign supply; whether the conditions of contract in Dublin had been recently changed so as to further enable this importation; whether the live stock hitherto supplied had given satisfaction to officers and men; and whether it was upon economical grounds that frozen and refrigerated meat was brought into a meat-producing country.

Mr. Campbell Bannerman said that the troops at the Curragh had only meat killed in the camp. Up to the end of this month the same system was applied to the Dublin garrison. In the rest of Ireland the troops might, under the contracts, the conditions of which were fixed in 1890, have 60 per cent. of foreign meat, but the actual quantity supplied could not be stated. He explained very fully on March 25th, in answer to the hon. gentleman, the changes about to be made as regards the Dublin garrison, and the reasons for those changes. It was not known that the live stock hitherto supplied for Dublin failed to give satisfaction, and the change of system was due entirely to the fact that the abattoir question was no longer necessary. A number of supplementary questions on this subject were addressed to the right hon. gentleman, and in the course of his answers to these he said that so long as those receiving the meat were aware that the amount of British meat was greater than might be tendered they did not keep any check. The percentage of 60 was no doubt fixed for a very good reason, although he did not know on what principle it was fixed. He should be afraid to assert that foreign meat was better than home meat; he understood that the cheapness of the former was the main element in the case.

The Manufacture of Beer.

The House at this sitting considered in Committee of Ways and Means the Budget resolution for the reimposition for another year of the extra sixpence per barrel duty upon beer, and Mr. Quilter proposed that the reimposition should not extend beyond beer brewed from substitutes for barley, malt, or hops. His object, he said, was to lighten the pressure of competition which affected the agriculture of this country and to do something in the direction of obtaining pure beer. The quantity of sugar used in brewing had risen at an enormous rate in recent years. In 1856 it was only 1,700,000 lb.; in 1866 the quantity had risen to 10,340,000 lb.; while in 1894 it had reached the gigantic figure of 245,731,432 lb. Taking two firms in the United Kingdom who brewed over 800,000 gallons, he found that while in 1822 they used 576 bushels of malt to each cwt. of sugar, in 1894 they only used 358 bushels. Another point the hon. member emphasised was the steady and considerable diminution of the specific gravity of

the beer made. The Chancellor of the Exchequer, speaking in reply to Mr. Quilter, said he could not consent to the proposal, because, in the first instance, four-fifths of the beer was made from malt and hops, and consequently the extra 6d. would not yield the money he required for the national expenditure. Worse than that, the proposal would involve an enormously expensive system of supervision in every brewery in the country. As to the question of specific gravity, there was no doubt that in these days the growing demand had been for lighter and brighter beer, and that demand had led to a great alteration in manufacture and to the increased employment of the chemist. It was really that and not any question of taxation which was the cause of the change that had taken place in the gravity of a large quantity of the beer now consumed. He understood that in most cases sugar was the material used for priming. It was this introduction of a certain amount of sugar which made the beer brighter and more palatable just before delivery, a process which seemed to suit the customer as well as the manufacturer. As to the other substitutes, he was told they were rarely used. He was informed that in addition to sugar a certain quantity of maize was used, but there was nothing unwholesome in that grain. It was feared in some quarters when the extra sixpence was proposed that it would lead to an addition of water. For a certain time that, he believed, was tried, but the experiment was not found to answer, and the result had been that, notwithstanding the imposition of the extra duty, brewers brewed quite as good beer as they did before the tax was imposed. After a time the proposal of Mr. Quilter was withdrawn and the resolution adopted.

MONDAY, MAY 13TH.

Anthrax in Leicestershire.

Mr. Herbert Gardner, answering two questions on this subject, said it was the case that an outbreak of anthrax, which led to the loss of two cows and a ewe, recently occurred on a farm at Arnesby, but the statements made as to loss and injury to human life appeared to have had reference to an outbreak which occurred nine years ago, and he did not gather that any such loss and injury had taken place on the present occasion. He was always very anxious to afford local authorities any assistance in his power, and the information the Board of Agriculture had issued on the subject of anthrax had been more than usually elaborate.

The Army Meat-supply.

Replying to a question on this subject Mr. Campbell Bannerman said that up to December, 1888, the trade in frozen or refrigerated meat had not been largely developed, and no restrictions had been found necessary on its supply. It was ascertained, however, that the contractors were issuing some of this meat mixed with home-killed meat, and as it was unquestionably a cheaper article—though not, as a rule, inferior in quality—it was decided that the State should have the benefit of the lower price by calling for tenders from contractors who were to be permitted to supply frozen or refrigerated meat not more than four days a week. In 1880 it was found more convenient to substitute a maximum quantity for a maximum number of days, and 60 per cent. was adopted as a rough substitute for four days out of seven. The percentage applied to each station at which foreign meat was supplied, and it included frozen mutton as well as refrigerated meat, but mutton must never exceed one-seventh of the total issue of meat. Mutton could be issued all the year round; refrigerated beef only from October to July inclusive. This period was extended last year, May having previously been the limit.

New Bills.

Among the new Bills introduced at the close of this sitting was one to extend the Merchandise Marks Acts to foreign and colonial cheese, and another to amend the law relating to the insurance of funeral expenses of children.

TUESDAY, MAY 14TH.

Accidents from Oil Lamps.

Mr. Bryce said, in answer to a question, that he had consulted with Mr. Mundella, the Chairman of the Select Committee on the Petroleum Acts which sat last session, and although he was unable to give a definite assurance at present, he hoped it might be found possible to reappoint the committee after Whitsuntide with a view mainly to considering the question of dangers arising from explosions of oil lamps.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on the Adulteration of Food Products held only one meeting this week, that is to say, on Wednesday, May 15th, when Sir Walter Foster presided.

Mr. Hudson, a provision merchant in London, was examined again with reference to the statement he made before the committee some time ago, that the inspectors of local authorities were open to bribery and did accept bribes. He explained that the witnesses he had in his mind when he made this statement were not prepared to come forward and have their names made public. Most of them were engaged in the wholesale trade and were supplying retailers with margarine, and they were willing to support the statement he had made if they could be heard *in camera*. He admitted that the statement was made on hearsay evidence, and that in the circumstances he was not in a position to substantiate it with absolute proof, although his opinion on the matter remained unchanged.

Mr. Nicholas Kilvert, managing director of Nicholas Kilvert and Sons, Limited, lard refiners, Manchester, gave evidence as representing the Manchester Chamber of Commerce and the Lard Refiners' Association, which, he said, comprised every refiner of American lard in Great Britain and Ireland. He supported a resolution which had been passed by the Manchester Chamber of Commerce, declaring that it ought to be lawful to use five per cent. of beef suet stearine in lard for stiffening purposes during six months of the year, say from April to September. The experience of the trade showed that it was impossible to dispense with this stearine during the cold season, and he regretted the action of the authorities in using the Food and Drugs Act to prevent the sale of lard so stiffened as strongly prejudicial to the public in whose interest the Act was passed. This addition could not in any sense be described as an adulteration. It hardened the lard, which for six months of the year, owing probably to the nature of the food on which the hogs were reared, was of an especially oily and liquid nature. The article required to be hardened before it was fit for carriage and consumption. At certain seasons of the year lard was of the consistency of cream, and

In no prosecution had a witness been brought forward who said that lard hardened by this stearine was in any way injuriously affected or depreciated. It met the requirements of the public, and was a perfectly pure article of food. To add lard stearine to raw lard, as had been suggested by some analysts, was practically the same as abstracting the oil of the lard, which was the best portion for the purposes of the public. It might fairly be compared with taking the cream from milk. Lard stearine, moreover, simply toughened without materially hardening lard, and when exposed to the air the oil continued to exude and waste. Beef suet stearine, on the other hand, absorbed the oil in which American corn-fed lard abounded. He denied altogether the right of the public analysts to adjudicate upon the question by deciding which method should be used.

Mr. John Irwin, member of a Liverpool firm of lard refiners, gave evidence of a corroborative character.

Mr. Alexander Leckie of St. George's House, Eastcheap, London, said he had been connected with the firm manufacturing Van Houten's cocoa for a number of years, and had been deputed by the London Chamber of Commerce to give evidence with regard to cocoa. The process of manufacture adopted by Van Houten's was of course a secret, but its object was to remove the excess of fat, and to further improve the cocoa in the matter of solubility and digestibility, natural cocoa being open to objection as an article of food. He did not think that the public were apt to be deceived if, as required by the Act, the mixture was labeled as being a mixture of cocoa, arrowroot, and sugar. The Act provided that the article should be of the substance and quality demanded. Altogether he thought the present state of the law was sufficient for the protection of the public.

The committee then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BARKER, A. H., L.R.C.P. Lond., M.R.C.S., has been reappointed a District Medical Officer by the Wantage District Council.

BARKES, R. S. FANCOURT, M.D., C.M. Aberd., M.R.C.P. Lond., has been appointed Consulting Physician to the British Lying-in Hospital, London.

BURY, E. C., M.D. St. And., M.R.C.S., has been reappointed Honorary Medical Officer to the North Cambridgeshire Cottage Hospital.

CALNE, DOROTHEA, M.B. Lond., has been appointed House Surgeon to the Children's Hospital, Hull.

CHRISTIE, J. F., M.B., C.M. Aberd., has been appointed Resident Medical Officer to the Aberdeen Royal Infirmary.

CLARK, A. W., L.R.C.P. Lond., M.R.C.S., has been reappointed Honorary Medical Officer to the North Cambridgeshire Cottage Hospital.

COCKBURN, W., M.B., C.M. Aberd., has been appointed Resident Medical Officer to the Aberdeen Royal Infirmary.

CUXON, S. A., L.D.S.R.C.S. Irel., has been reappointed Honorary Dental Surgeon to the North Cambridgeshire Cottage Hospital.

DALTON, A. J., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer for the Hendred Sanitary District of the Wantage Union.

GARLAND, E. C., L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health for the Borough of Yeovil.

GRAY, H. M. W., M.B., C.M. Aberd., has been appointed Resident Medical Officer to the Aberdeen Royal Infirmary.

HARDING, L. N., B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Brighton, Hove, and Sussex Throat and Ear Hospital.

HUNTER, WILLIAM, M.D. Edin., M.R.C.P. Lond., M.R.C.S., has been appointed Pathologist and Curator of Museums to the Charing-cross Hospital.

HUSKARD, C., M.R.C.S., has been reappointed Medical Officer of Health for the City of Ripon.

MCCLELLAND, W., M.B., Ch.B. Vict., has been reappointed Non-Resident Medical Officer to the Gynaecological Department of the Liverpool Royal Infirmary.

ROPER, LEONARD, M.A., M.B., B.C. Cantab., has been reappointed Clinical Assistant and Demonstrator in the Throat Department at Guy's Hospital.

SHEN, A. W., M.D. Lond., B.S., F.R.C.S. M., L.R.C.P., has been appointed Assistant Surgeon to the Cardiff Infirmary.

STANTON, W. E., L.S.A. Lond., has been appointed Medical Officer for the Deeping St. Nicholas Sanitary District of the Spalding Union.

TAYLOR, J. C., M.D. Edin., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Westbury and Whorwellsdown District.

TAYLOR, LEO, F.I.C., F.C.S., has been appointed Public Analyst for Hackney, in succession to the late Dr. Tripe.

TREASURYWALA, E. J., M.D., L.R.C.P. and S., has been appointed Assistant Electrician at St. Bartholomew's Hospital.

VALLANCE, H., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer by the Chelsea Board of Guardians.

WARRACK, J. S., M.B., C.M. Aberd., has been appointed Resident Medical Officer to the Aberdeen Royal Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ACCRINGTON MEDICAL DISPENSARY.—Qualified Medical Man.

ASYLUM FOR IDIOTS, Earlswood, Redhill, Surrey.—Assistant Medical Officer. Salary £150 a year, with board and residence. Applications to the Secretary, 36, King William-street, London-bridge, E.C.

BIRKENHEAD UNION.—Medical Officer and Assistant Medical Officer of Workhouse and Schools. Salary of the Medical Officer £30 per annum for the Workhouse and £10 for the Schools, with extra medical fees as prescribed by the Local Government Board. The Medical Officer will also be appointed Public Vaccinator of the Workhouse and Schools at a fee of 1s. 6d. per case of successful primary vaccination. Salary of the Assistant Medical Officer will be £65 per annum for the Workhouse and £20 for the Schools, with rations, attendance, washing, and residence in the Workhouse. Applications to the Clerk to the Guardians, 45, Hamilton-square, Birkenhead.

BLACKBURN AND EAST LANCASHIRE INFIRMARY, Blackburn.—Junior House Surgeon. Salary £50 per annum, with board, washing, lodging, &c.

GLAMORGAN COUNTY ASYLUM, Bridgend.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board (no beer or wine), lodging, washing, and attendance.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Pathologist and Registrar for one year. Honorarium, 50 guineas per annum.

HALIFAX INFIRMARY AND DISPENSARY.—House Surgeon, unmarried. Salary £80 per annum, advancing £10 per annum up to £100, with residence, board, and washing.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London, W.—Senior Clinical Assistants.

LIVERPOOL STANLEY HOSPITAL.—Junior House Surgeon. Salary £70, with board, &c.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—House Physician for six months. Salary at the rate of £20 per annum.

PARISH OF BIRMINGHAM.—Resident Medical Officer at the Workhouse. Salary £150 for the first year, rising £10 yearly to £200 per annum, with rations, apartments, washing, and attendance. No alcoholic liquors are allowed in the rations. Applications to the Clerk to the Guardians, Parish Offices, Edmund-street, Birmingham.

PARISH OF ST. LEONARD, Shoreditch.—Second Assistant Medical Officer for the Infirmary, Hoxton-street, N. Salary £40 per annum, with rations, furnished apartments, and washing in the Infirmary. Applications to the Medical Officer, 204, Hoxton-street, London, N.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, London.—Professors and Lecturers.

ROYAL FREE HOSPITAL, Gray's-Inn-road, W.C.—Two Resident Medical Officers for six months. Board, residence, and washing provided.

SOCIETY OF APOTHECARIES.—Examiners. Applications to the Clerk to the Society, Apothecaries' Hall, Blackfriars, E.C.

ST. LUKE'S HOSPITAL, London, E.C.—Clinical Assistant for six months. Board and residence provided.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Lecturer on Mental Diseases.

THE BOARD OF WORKS FOR THE HOLBORN DISTRICT (IN THE COUNTY OF LONDON).—Medical Officer of Health for the Holborn District. Salary £350 per annum. Applications to the Clerk to the Board, Holborn Town Hall, London, W.C.

THE HOSPITAL FOR WOMEN (THE LONDON SCHOOL OF GYNÆCOLOGY), Soho-square, W.—Clinical Assistants.

THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo Bridge-road, London, S.E.—Clinical Assistant and Anesthetist for six months. Salary at the rate of £30 per annum.

UNIVERSITY COLLEGE, London.—Professorship of Materia Medica and Therapeutics.

WESTERN GENERAL DISPENSARY, Marylebone-road, London.—Junior House Surgeon, unmarried. Salary £50 per annum, with rooms and board.

Births, Marriages, and Deaths.

BIRTHS.

SHACKEL.—On May 6th, at Ludlow, the wife of G. A. Shackel, L.R.O.P., M.R.C.S., of a son, stillborn.

SNODGRASS.—On May 11th, at Victoria-crescent, Down-hill, Glasgow, the wife of William Snodgrass, M.A., M.B., of a son.

WILLS.—On May 14th, at Lower Seymour-street, Portman-square, W., the wife of W. A. Wills, M.D., of a son, stillborn.

MARRIAGES.

BETTS-BAYLIS.—On May 8th, at St. Mary's Church, Farnham Royal, Bucks, Robert Sidney Betts, L.R.C.P., M.R.C.S., of 157, Junction-road, N., to Florence Jane Baylis, daughter of the late Captain Henry Ingle Baylis, 3rd Goorkha Bengal Infantry.

HILL-GREEN.—On May 15th, at the King's Weigh House Chapel, Duke-street, Grosvenor-square, William Byron Hill, M.R.C.S. Eng., to Emma Hunsdon, eldest daughter of the late Thomas Moses Green.

ROBINSON-HARRISON.—On May 1st, at St. Joseph's Church, Cairo, Oliver Long Robinson, Surgeon-Captain A.M.S., son of the late H. O. Robinson, Esq., of Dublin, to Rose Adela Harrison, daughter of the late Sir Henry Harrison, B.C.S., West-hill, Sydenham.

DEATHS.

DAVISON.—On May 10th, at 1, Berkeley-square, W., May, wife of W. Marshall Davison, M.B., daughter of the late Rev. Kylie Ernie Aubrey Money.

FOSTER.—On May 10th, at Oxford House, St. John's-park, Blackheath, the residence of his sister, Dr. N. S. Foster, of Sussex-place, Onslow-square, London, W.

LOYD.—On May 10th, at his residence, Robert Hodgkins Lloyd, M.D., M.R.C.S., L.S.A., Medical Superintendent Lambeth Infirmary, aged 47 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—MEDICAL SOCIETY OF LONDON.—Annual Conversation. Oration at 8.30 P.M. by Mr. A. Pearce Gould on "The Recent Evolution of Surgery."

TUESDAY.—PATHOLOGICAL SOCIETY.—8.30 P.M. Dr. Vaughan Harley: Absorption and Metabolism in a case of Pancreatic Obstruction.—Mr. Edmunds: Observations and Experiments on the Pathology of Graves' Disease.—Mr. A. T. Collum (introduced by Dr. Pitt): Imperforate Duodenum.—Mr. S. G. Shattock: Diphtheria and Pseudo-diphtheria Bacilli from Two Sisters Simultaneously Affected.—Mr. H. J. Waring: Actinomycosis of the Cheek.—Mr. Herbert Snow: Malignant Reversion of Cystic Fibromata.—Mr. Shattock: Cultural Variations of Streptococcus Pyogenes. Recent Specimens.—Mr. L. Hudson: A Series of Specimens of Ulcerative Colitis from cases of Swine Fever. Card Specimens by Messrs. Fletcher, Paget, Battle, and Mackenzie.

FRIDAY.—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Annual General Meeting. Report of Council; Election of Officers. Papers:—Dr. Lucas Benham: Thickened and Contracted Mesentery simulating Tumour in a case of Cirrhosis of the Liver.—Dr. Sidney Phillips: A case of Splenic Abscess; Secondary Suppuration in the Liver; Death from Pyæmia.—Dr. S. West: A case of Recovery from Tuberculous Meningitis.—Mr. Battle: Calculus of Kidney associated with Simple Growth of the Renal Pelvis; Nephrectomy; Nephrectomy.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 1 P.M., Mr. A. S. Morton: Affections of Eyelids.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. Wilkin: Aural Polyp.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Hyslop: Stupor, Catalepsy, Kataplexia, Dementia.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers.

LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 P.M., Mr. A. Quarry Silcock: Progressive Myopia, with illustrative cases.—Hospital for Skin Diseases, Blackfriars, 1 P.M., Dr. Payne: Herpes, its Varieties.

THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Mr. B. Pitts: Abdominal Surgery in Children.—National Hospital for the Paralyzed, Bloomsbury, 8 P.M., Dr. Buzzard: Multiple Neuritis.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. S. Mackenzie: Cases in the Wards.

FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 5 P.M., Prof. Crookshank: Anthrax and Malignant Oedema.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Craig: Delusional Insanity, Paranoia.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular in question.

HUMORAL PATHOLOGY I.

A CORRESPONDENT sends us the following "cure for jaundice":—"Bury the first water after 12 o'clock with one ounce of blue stone vitriol. Get one quart of tenpenny ale, one lemon, and a pennyworth of cake saffron. Stew down to three gills. When cold get twopennyworth of sweet nitre, put in, and take a wineglassful three times a day. On the third day take a dose of castor oil."

Mr. Harvey B. Bashore.—Messrs. Byre and Spottiswoode, 32, Abingdon-street, Westminster, London, S.W.

Mr. J. E. Hall.—We do not prescribe or recommend practitioners.

ALLEGED TOUTING BY A PUBLIC VACCINATOR.

To the Editors of THE LANCET.

SIRS,—Will you kindly advise me, first, as to whether the following is not a gross breach of medical ethics; secondly, as to what, if anything I should do in this case?

In my village is residing the assistant of a medical man who lives in the neighbouring town (two miles distant). This assistant is the public vaccinator, and in this capacity is continually calling on my patients and asking them if they will permit him to vaccinate their babies—babies I have brought into the world, and whose parents in the majority of cases call me in to vaccinate. I would altogether ignore this if this person had not caused great annoyance by calling on some of my best patients, who have complained to me of this annoyance.

I am, Sirs, yours faithfully,

May 14th, 1895.

C. H. E.

*. It is quite indefensible, and, as far as we know, unprecedented, for a public vaccinator to tout for the patients of another medical man. The aggrieved practitioner should remonstrate very emphatically, and if this is not heeded should complain to the Local Government Board.—ED. L.

"THE LATEST MEDICAL GUIDE TO HARROGATE."

OUR attention has been drawn to an advertisement under the above title in the Harrogate Advertiser of May 11th of a book by "Dr. Myrtle and Dr. J. A. Myrtle, J.P.," "with cases." The experience of these gentlemen with regard to the use of the Harrogate water is well known, and it is natural that they should seek to publish it; but we are of opinion that publication in the above form is not so unobjectionable as in the form of a medical treatise or through the medical journals. The authors are doubtless unaware of the manner in which the book is advertised.

Further subscriptions are earnestly requested, and will be received and acknowledged by the Rev. H. Townshend, 41, King Henry's-road, South Hampstead, N.W.

Dr. J. H. Gramshaw.—The returns of the Registrar-General are quite correct respecting the great number of deaths from small-pox in Calcutta—namely, 872—within the eight weeks ending with March last. In fact, the Registrar-General's figures really understate the gravity of the case; for the reported deaths are those only that occurred in the city of Calcutta, the population of which at the 1891 census was 466,460, and are exclusive of the deaths taking place in the suburbs, which contain an additional population of 215,100. Small-pox has certainly been epidemic in Calcutta for some weeks past at any rate, the number of deaths taking place in the months of February and March last having risen almost steadily from 58 in the week ending Feb. 9th to 171 in the week ending March 25th. In the last week of which we have as yet any record—namely, that ending March 30th—the number of deaths from small-pox was 153. Of this total of 872 deaths not fewer than 671 occurred within the more recent five weeks of the above specified period, so that the epidemic may not even yet have reached its height. The vast majority of the deaths from small-pox were amongst Asiatics, principally either Hindoos or Mahomedans, only a few comparatively speaking having been reported amongst non-Asiatics.

Dr. Lyander Maybury.—We prefer the name at the bottom of the paper, but we scarcely think it can be made a question of ethics; it is a matter of taste.

B. O. N.—There is no rigid rule in such matters. A medical man is quite at liberty to charge a druggist as he would any other patient.

"A CASE FOR DIAGNOSIS."

To the Editors of THE LANCET.

SIRS,—I would suggest to "M.D. Edin.," who sends you a case for diagnosis, the possibility of his patient having taken a preparation containing coca or cocaine. Wines and elixirs of coca, voice lozenges, &c. containing cocaine are often taken by patients on the advice of friends without any reference to the medical advisers, and in case of intolerance the fact might be concealed in perfect good faith through a conviction, founded on past experience in others, of the absolute harmlessness of the preparation. Although the importance of idiosyncrasy in connexion with coca is well known, I do not think the extreme extent to which susceptibility is pushed in some cases is generally realised. I have seen very alarming symptoms result from fractional doses of a grain of the alkaloid, and I passed the better part of the night on one occasion with a young lady who had taken two or three teaspoonfuls of a liquid extract of coca that a friend with whom she was living took to the same extent several times a day. The feeling of impending death, the rapidity of the pulse, and a suspiciousness of the respiration would exist in such a case, as well as pallor, perspiration, and a condition of moral as well as physical shakiness. The temperature may be decreased or heightened. Several times I have heard patients in this condition speak of seeing the light as through a fog, one describing the candle flame as appearing surrounded by a lunar rainbow. Finally, the metrorrhagia is in harmony with the theory. In the early days of cocaine I was told as a warning of a case where the application of a solution to the os uteri for the relief of pain was at once followed by abortion.

I am, Sirs, yours truly,

Paris, May 13th, 1895.

OSCAR JENNINGS.

To the Editors of THE LANCET.

SIRS,—I had a very similar case to the one mentioned by "M.D. Edin." in THE LANCET of the 11th inst. The symptoms came on two days after confinement, lasted six hours, and gradually disappeared. My patient had lived in India for years, and suffered from ague. I put her on large doses of quinine with the desired effect. I may mention that she had only arrived from India two months previously. In my opinion it was an ordinary attack of ague, which in her then condition occasioned the other symptoms.

I am, Sirs, yours truly,

May 13th, 1895.

M.B. EDIN.

RUPTURE OF THE PERINEUM.

To the Editors of THE LANCET.

SIRS,—Can you tell me if there has been any case in which an action for damages caused by rupture of the perineum during labour has been successful?

I am, Sirs, your obedient servant,

May 13th, 1895.

PERINEUM.

THE ADVERTISING EPIDEMIC—A NEW SPECIMEN.

We give the following instances, in their setting and relation, from the *Sutton Coldfield and Erdington Times* of April 27th, 1895. The middle advertisement seems to have no connexion with the others, but it shows into what strange company medical men get when they find themselves in the advertising columns of newspapers:—

"At the recent Examining Board in England by THE ROYAL COLLEGE OF PHYSICIANS OF LOND., and the ROYAL COLLEGE OF SURGEONS OF ENGL., MR. FRANK COOPER (son of Dr. Cooper, Erdington) PASSED the Examination in Chemistry, having previously passed in Materia Medica, Therapeutics, Pharmacy, Anatomy, and Physiology."

"THE CEMETERY, SUTTON COLDFIELD.—WANTED, a young Man to assist the Sexton generally. Must have some knowledge of gardening. Local person preferred. Wages 16s. per week.—Apply in writing to Clerk, Burial Board, Sutton Coldfield."

"DR. COOPER, Surgeon, Six Ways (opposite Baptist Chapel), Erdington. Scale of charges: Advice and medicine, 1s. 6d.; for children, advice and medicine, 1s.; visits within one mile from the surgery, 1s.; vaccination, 1s.; midwifery fee, 15s.; medical notes issued which entitle the patient to attendance and medicine for one week, 6s.; ditto for children, 3s. 6d. Surgery hours: Morning from 9 till 11; evening from 6 till 9."

Mr. W. Mason.—There have been numerous experiments made with regard to the production of immunity against swine erysipelas, hog cholera, and swine fever, some of which have been recently published in America by Theobald Smith, whilst others have been published by Metschnikoff, Seelander, and others. The Pasteur Institute sends out a protective material to be used against rouget, so that there has already been considerable work done in this direction.

AN OPHTHALMOLOGICAL HINT.

To the Editors of THE LANCET.

SIRS,—I have found the following manoeuvre of use in applying solutions to the conjunctive of nervous patients. The patient is seated, the head extended at right angles to the trunk and the eyelids closed. Several drops of solution now form a little pool over the inner canthus, and on opening the eyelids the solution flows gently over the conjunctiva, stays there as long as required, and the difficulty of spasmodic closure of the eyelids is avoided.

I am, Sirs, yours faithfully,

May 10th, 1895.

F. HYDE MANKLEY, M.D. Dub.

MEDICAL AID ASSOCIATIONS.

We do not consider it satisfactory for a medical man to have his name associated with purely commercial undertakings, supplying medical attendance practically to all comers for 1d. per week to adults and a halfpenny per week to children. It does not promote the interest of the working classes, and certainly does not promote the dignity of the profession, that the medical attendance of the working classes should be arranged in such a wholesale way and on such low terms by companies which are even less defensible than the ordinary medical aid associations, which have had a local evolution out of pre-existing friendly societies.

H. A. B.—Inquiry must be made at the offices of the companies mentioned and at the colonial agencies for the respective countries.

INTRA-LARYNGEAL INJECTIONS.

To the Editors of THE LANCET.

SIRS,—I shall be glad of any information as to the intra-laryngeal injection of menthol and guaiacol for tuberculous disease of cows—strength of solution, dosage, &c.—I am, Sirs, yours obediently,

May 13th, 1895.

TRACHEA.

"INJUDICIOUS FRIENDS AND NEWSPAPER PUFFS."

Mr. C. S. Pantin.—We gladly and readily accept the assurance of our correspondent, and of the paper on whose paragraph we commented, that he was no party to it. At the same time we sympathise with him as the subject of it.

Indignant.—We have sent the pamphlet to the police authorities.

During the week marked copies of the following newspapers have been received:—*Portsmouth Times, Lytham Times, Toronto Mail, Hampshire Herald, Doncaster Gazette, West Lothian Courier, Manchester Courier, Gloucester Chronicle, Bolton Chronicle, Lowestoft Standard, East Anglian Daily Times, Manchester Guardian, Sheffield Telegraph, Birmingham Gazette, Torquay Times, Western Morning Gazette, Walsall Observer, Bristol Times, Brighton Gazette, Southport Guardian, Bedfordshire Express, Chorley Guardian, Sleaford Journal, Ashbourne News, Globe, Echo, Literary World, Harrogate Advertiser, Reading Mercury, Weekly Free Press and Aberdeen Herald, Times of India, Builder, West Middlesex Standard, Science, Pioneer Mail, Architect, City Press, Local Government Chronicle, Yorkshire Post, Hertfordshire Mercury, Le Courrier de la Presse, Liverpool Daily Post, Guy's Hospital Gazette, Bristol Mercury, Surrey Advertiser, Leeds Mercury, Local Government Journal, Mining Journal, Isle of Wight County Press, Peterborough and Hunst Standard, Kent Times, Scotsman, Kelso Mail, Moffat News, The World, Grimsby News, Banffshire Advertiser, Goolie Times, Brighton Society, Invergoron Times, Royal Cornwall Gazette, Staffordshire Post, Kenilworth Advertiser, &c., &c.*

Communications, Letters &c. have been received from—

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only holds a ready means of finding any notice, but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

In Address

ON THE

RECENT EVOLUTION OF SURGERY.

Being the Annual Oration, delivered before the Medical Society of London, May 20th, 1895,

By A. PEARCE GOULD, M.S. LOND.,
F.R.C.S. ENG.,

SENIOR ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL AND SURGEON
TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

MR. PRESIDENT AND GENTLEMEN,—I am using no empty form of words when I say that our gathering this evening has lost much of its wonted pleasure from the absence from among us of one so long and so prominently identified with this society as Mr. Durham was. In a remarkable degree Mr. Durham was the very personification of the great characteristics of the Medical Society of London, for he combined intellectual keenness and ardour in his profession with intense warmth of heart and kindly feeling. Everyone knew him as the skilful surgeon and the very soul of honour; but we here knew him also as the wise administrator and the genial friend. When our President eleven years ago Mr. Durham gave us of his very best in time, in thought, and in effort, and made us ever his debtor; but he has placed the society under a still greater debt of obligation by his ten years of service as its treasurer. We owe it largely to his genius, which combined enterprise with caution, that we are now more handsomely accommodated and more financially prosperous than at any former time in our history. Many of us remember the striking and valuable oration which Mr. Durham gave fourteen years ago. His subject was the Surgery of the Future, and in his address he sketched out the lines along which the art he loved so well—and which he himself adorned—would progress in the immediate future. It is a striking testimony to his accurate appreciation of the new forces at work that he then foretold much of what has since been realised.

The subject that I have ventured to choose as my theme is the Recent Evolution of Surgery. I have selected it because, however unworthily I may deal with it, the subject, at any rate, is well worthy of attentive study. This has been true at every stage in the long history of our art, but never so true as to-day, and for those who, like myself, have had the opportunity of witnessing during the last twenty-five years such a development in surgery as has never occurred before in a generation—nay, not even in a century or a millennium. The origin of the surgical art is lost in the obscurity of prehistoric times, but for two thousand years at least we are able to trace more or less clearly and fully its onward march. Its progress has been slow and at times intermittent. The light of science has shone more brightly now here, now there, and great local schools have risen to fame, and then, alas, sunk into oblivion. Although the progress has been slow it has been assured, and at almost any time in the history of the art we can imagine an orator addressing his fellows and asserting with truth that the present was better than the past. This reflection may well give us confidence in the future, and temper our boasting of the present with the expectation of the greater things still to be realised.

It is possible to measure the progress of our art either by the growth in the ideas to which it gives expression or by the improved expression it gives to old ideas. Of method we find an almost infinite variety, and few surgeons are so devoid of all originality as not to add something to the constant advance of surgery as an applied art. The great principles and thoughts of surgery are few, and it is given only to nature's giants to develop or to correct them. By whichever standard we judge the progress of surgery within the last twenty-five years we shall be bound to admit that never before was the advance so general, so rapid, so beneficent. Inasmuch as mind is more than matter, and in the degree in which a truth is greater than any expression of it, the highest and truest standard by which we can estimate the progress of an art will always be the moral rather than the merely material. I believe the chief glory of this period

No. 3743.

lies in the almost entire transformation of surgical ideals that has occurred rather than in the improved methods of expressing them. In this sense it may with justice be called the "golden age of surgery," and to apply to it the poor term "progress," which we also use for the slow march onward of the last 2000 years, is altogether inadequate and therefore to some extent misleading. I have therefore ventured to use the word "evolution" to express this wonderful unfolding, enlarging, ennobling of the thought, spirit, aim, and ideal of surgery, in distinction to improvements in its methods only, which may well enough be connoted by the poorer word "progress." I propose, then, to show to what extent and in what direction the very life of surgery has undergone a striking evolution within the last twenty-five years. I shall ask you to test the position of surgery to-day, as compared with what it was when most of us first began its study, by its new estimate of the bearing of anatomical facts; by its higher regard for the integrity of the organism; and by its altered conception of its place and value as a healing art.

1. One great change that has come over surgery is the removal of the formerly admitted anatomical restrictions upon surgical operations. This is sometimes spoken of as the extension of surgery into new regions, and it is pointed out that organ after organ has been, as it were, captured by surgeons and shown to be a more or less fruitful field for their enterprise. That, I think, is but a very imperfect expression of the facts, and one that conceals their true significance. For what are the facts? We are all familiar with them. The operation of trephining probably dates from prehistoric times, and from that remote period up to a very recent day surgeons have confined their cranial operations to removal of more or less of the skull, and have most carefully abstained from interference with the brain within. Quite recently trephining has sunk in importance, and is now, as a rule, only an incident in an operation directed entirely to active treatment of the membranes and brain. Similarly, while our immediate predecessors operated timidly, if at all, upon the posterior part of the spinal column, we operate upon the spinal membranes and cord, and also occasionally upon the anterior part of the vertebral column. Of the surgery of the thorax the same holds true. Operations upon its walls were sanctioned long ago, and timid efforts were made occasionally to open and even drain the pleura, but the thoracic wall only was regarded as the legitimate field of surgical interference. Now, not only is the pleura a common field of successful surgical interference, but the lung itself is freely operated upon, and the chief bar to a much greater development of pulmonary surgery is the difficulty attending the minutely precise diagnosis and localisation of the diseases of this organ. The pericardium is aspirated or drained without hesitation, and the suggestion has been made not only to tap the heart itself, but to treat wounds of its muscular substance by careful suture in just the same way as similar injuries of other muscles. The mediastinum, too, has been brought within the pale of legitimate surgery. No single organ in the great cavity of the abdomen is now held to be beyond the reach of the surgeon's knife. The successful removal of huge abdominal tumours, which at first excited angry opposition and then admiring wonder, is now a commonplace event in every operating theatre in the world. This has been followed by the extension of surgical methods to one and another of the solid and hollow abdominal viscera, until now liver, spleen, kidney, stomach, and intestines, uterus and its appendages, gall-bladder and bile-ducts, ureters and urinary bladder, and even that most inaccessible of organs the pancreas—one and all have their own surgical history and triumphs. In other words, the field of direct surgical interference was formerly limited to the limbs and to the common coverings of the great cavities of the trunk, to the exclusion of the great serous membranes and the organs contained within them. Surgeons were content to recognise that many organs and parts of the body lay beyond the limits of legitimate surgical interference, and they admitted it to be no reproach to their art to refuse to interfere with the peritoneum, the kidney, the lung, or the brain. I submit that it is essential to a correct appreciation of the change that has occurred to notice that the advance has not been gradually or slowly made, but occurred practically simultaneously all along the line. Its explanation lies not nearly so much in increased momentum in surgical art as in a sudden removal of a restriction to its advance. Surgeons are not bolder now than in the past, and although their anatomical knowledge has in

x

many directions been made more precise, and they are possessed of operative aids unknown to a former generation, it is not chiefly in these influences that we must seek an explanation of the fact we are considering, but in the removal of a barrier raised and supported by ignorance and misconception. It arose partly from a belief that a surgical operation is in its very nature lethal, what we now call pathogenic, but largely from the view that certain tissues and organs of the body are of such anatomical delicacy, and so little endowed with either power of repair or ability to resist injurious influences, albeit that they are of prime importance in the animal economy, that to submit them to operation was to court certain disaster. He who saw the removal of a subcutaneous fatty tumour entail suppuration and the risk of blood poisoning could not contemplate with approval the removal of a kidney. When the surgical wound of a healthy joint was seen to be attended with the gravest risk to limb and even life, how could a surgeon dare to lay open and operate freely upon a huge serous sac like the peritoneum? When every surgical procedure entailed grievous risk and no means were known of certainly avoiding it, all surgeons felt the necessity of limiting operations to the irreducible minimum, and when it was forced upon them that the deeper their incisions the greater the peril, what else could they think than that the mere depth of an organ and the means taken by nature to protect it from external violence were a clear intimation of its being beyond the scope of surgery? Thirty years ago the body was mapped out into an operable area and an inoperable area, the distinction being based upon anatomical position and differences; but when surgeons understood the process of healing of uninfected wounds such an anatomical classification of parts became meaningless, and a great barrier to the progress of surgery was at one moment removed. To-day we know that simple, well-executed surgical procedures are not in themselves the cause of disease (pathogenic), and that every tissue and organ of the body is the seat of a power of repair more than equal to the demand surgery makes. With this knowledge the whole anatomical barrier to the progress of surgery has vanished, and the problem has assumed an entirely different aspect. From an anatomical standpoint the only bar to the feasibility of an operation is its mechanical impossibility. But I must guard myself from being understood to maintain that to-day a surgeon is free to incise anywhere or to excise anything. That can never be. The very removal of the anatomical restrictions upon the activity of surgeons has brought into relief the physiological restraints upon their art. Thus while the depth and important relations and the anatomical structure are no bar to the excision of either kidney, the physiological importance of the organs is an absolute bar to double nephrectomy or to the removal of a single kidney when its fellow is *hors de combat* from disease. A wandering spleen has been successfully excised, and such an operation is distinctly indicated where the organ gives rise to serious trouble from torsion of its pedicle; its place in the organism can be adequately filled by the bone-marrow, aided possibly by the lymphatic glands and sometimes by small masses of spleen tissues left behind in the gastro-splenic omentum. But, so far as we know, a wandering liver can never be treated in the same way; anatomically the operation is almost equally feasible, but physiologically it is barred. Similarly, cerebral surgery is at present limited to the relief of pressure upon its substance, the excision of morbid growths at or close to the surface, and the evacuation of abscesses in its substance. With our present knowledge we have to admit that the medulla oblongata and the central portions of the brain are outside the field of surgery, not because they cannot be reached or on account of any peculiarity of structure, but because of their physiological importance. The only limit in the anatomical range of its activities that a surgeon now recognises is the physiological one. He no longer asks himself whether this, that, or the other structure is too delicate to be the field of his interference, but only whether he can operate upon it without injury to structures necessary to life or without inflicting upon the patient greater disabilities than those caused by the disease or injury he seeks to combat. Thus the surgeon views the human body as a field for operations from an entirely different standpoint from that occupied less than a generation ago; we of to-day cannot put ourselves, even in imagination, quite into the mental attitude of those who immediately preceded us. In this new thought, then, we see one great sign of the evolution of surgery.

2 Closely connected with this change in surgical thought, and yet to some extent standing in contrast with it, is the higher regard in which the physiological integrity of the organism is now held. While no one tissue or organ is now held by surgeons to be beyond the scope of their activities, all tissues and organs have assumed an altogether new and higher sacredness in their eyes. To use a time-honoured but much abused phrase, surgery has become more entirely conservative in its aims than was ever the case before. It is true that diseased structures are removed with greater freedom than ever and almost regardless of their situation; but never before have we seen such efforts as are now made to limit operations to the removal of diseased parts and to save all healthy structure. I will mention four examples of the influence of this new spirit in surgery.

(a) My first example is found in the diminished frequency with which amputation is resorted to for injuries and diseases than at any former period. I will not attempt to prove this by statistics, for they are in great measure useless for the purpose. Indeed, I think it quite possible that if we appealed to statistics only we might meet such an awkward fact as this—that more thighs were amputated at a given hospital last year, let us say, than was the case twenty years ago. For while amputation for some affections has been replaced by happier methods of treatment, we must not forget that with greater safety attending all surgical operations there are other series of cases which were before deemed hopeless, even at the cost of an amputation, which are now so treated. Statistics may be good servants, but they are always bad masters. They are capable at the best of expressing only the grosser facts of human experience, and, as a rule, with much error bound up with their mathematical accuracy. The best of life cannot be measured and weighed, and were the statistical method the only one, or the chief, which showed the recent progress of the surgical art, the title of my address would be a misnomer, for of evolution mere numbers can tell us nothing. When a statistician has said his last word on a man's height, bulk, weight, age, and fortune, we are still in total ignorance of the man himself, his true personality and value. And so with surgery. The aims of surgery cannot be weighed and measured; the soul of surgery is as impalpable as the ether. Not for proof, then, but to gratify curiosity, and also that you may not think that these remarks are inspired by a suspicion that the so-called "facts" are against me, I have taken out the amputation statistics as given in the Surgical Registrar's Reports for Middlesex Hospital of the last two years, and compared them with those given in the similar reports for 1873 and 1874. I find that in this institution in the two years 1873 and 1874, 2382 patients passed under the surgeon's hands, upon whom 590 operations were performed, including 39 major amputations—by a major amputation I mean all amputations except those of the digits of either limb; twenty years later, 1893 and 1894, when the number of patients had risen to 2957 and the operations were 1554, the major amputations had fallen to 34. In other words, while 16 per 1000 of the patients treated by the surgeons in this institution twenty years ago suffered amputation, to-day the proportion so maimed has fallen to 11 per 1000. Twenty years ago 6.6 per cent. of the operations in this hospital were amputations; to-day only 2.1 per cent. are of this nature. These figures are small and not specially selected, and I do not quote them as anything more than a rough mathematical expression of a fact familiar to us all—that amputation has become much less frequent in surgical practice within the very recent period we are now considering. What a fact that is. A great and wholly undeserved glamour has been thrown around the operation of amputation. The interest attaching to its design and execution, and to the construction of a sound and useful stump, has done much to obscure the fact that amputation at best is a confession of failure, a refuge of the destitute. We have to admit that at times it is an inevitable step and may be a great boon to the patient, saving his life or health, or freeing him from the encumbrance of a painful and useless member; but all the same, it is a therapeutic tragedy, an irreparable disaster. Now, not so long ago surgeons took a special interest, even a pride, in their cases of amputation. To-day, I venture to say, there are no operations in surgery that excite less enthusiasm than amputations, none which are felt to be more opposed to the whole spirit of surgical art; and a surgeon rarely approaches one without not only a certain misgiving, but a painful sense of disappointment, if not of failure. The

readiness with which he resorts to amputation is recognised to be a rough working test of a surgeon's unfitness to practise his art. This is not only a great fact. It is the outward and visible expression of a great change which has passed over the whole mind and spirit of surgeons. There is more to interest an intelligent surgeon in the progress of a case of amputation to-day than there was twenty years ago; but to him this interest is dwarfed into littleness by the violation of one of his most cherished instincts in the sacrifice of healthy living parts in an effort to save or benefit the individual. What is true of amputation of limbs is equally true of the removal of organs, although in some cases the advance here has not been so great. But I can at least point to excision of the thyroid gland replaced by enucleation of tumours of that organ; and to the removal of tuberculous deposits from the testicle and even from the kidney in place of excision of these organs.

(b) My second example I find in the *higher standard of excellence we strive to attain in the repair of injuries and operation wounds*. Where twenty years ago we only aimed at our patient's recovery, and the final closure of a wound, we now look for perfect restoration both of structure and function. An incident that occurred in this room nearly twelve years ago is indelibly impressed upon my memory. The greatest of living surgeons had read a paper in which he described and advocated his then novel treatment of the direct suture of the fragments of a transverse fracture of the patella. Of the discussion that followed only one speech has lived in my recollection: it was that of a distinguished surgeon and leading teacher, nearly twenty years Sir Joseph Lister's junior, who told him, in his terse phraseology, that the operation was magnificent but it was not surgery. Not surgery! The idea of obtaining perfect structural repair of an injured part was so foreign to the thoughts of even our foremost surgeons that this successful effort to grapple with an injury that often permanently crippled its victims was condemned as unsurgical, the object aimed at was considered outside the pale of legitimate enterprise and comparable only with the heroic but mistaken Balaklava charge. The ideal then falteringly held up before us by Sir Joseph Lister, and which at first was entertained by so few, is now cherished by all and firmly possesses the mind of every true surgeon. All do not strive to attain it by the same road; that matters not; the idea of obtaining perfect repair of injuries has been grasped, and this has raised at a bound our standard of surgical excellence. See what it has led to. Other fractures than that of the patella are now submitted to direct suture if perfect repair cannot be obtained by our older—shall I say antiquated?—methods of treatment. Dislocations which could not be replaced by external manipulation used to be left; the surgeons had exhausted their resources when ropes and pulleys failed to drag back the errant bone, and they were content to leave the case to unaided nature. Now no one would consent to utter such a *non possumus*, but would at once replace the bone by operation. In obedience to the same impulse, the so-called "internal derangements of joints" are submitted to operation. This ideal finds another expression in the care now taken in the suture of wounds where many structures are divided. Where formerly surgeons spoke and thought merely of bringing the edges of a wound together, they now speak and think of the careful union of divided structures so as to obtain the most perfect repair. In the surgery of the abdominal wall the beneficial result of this suture of its different layers is very marked, and even such a detail as the splitting of the aponeurosis of the external oblique muscle in place of division of its fibres is not only attended to, but is found to be worth attending to. Another recent improvement of the same kind is the exact and sutured suture of the divided tissues in cases of external urethrotomy, to secure perfect primary healing of the wound in place of the older and very disagreeable method of allowing the wound to slowly fill up. Surgeons have ceased to view with approval the slow healing up of their wounds by the laborious process of granulation, and this not only because that process is slow, but because it fails to restore the parts in the same perfect way that "primary union" does. I might adduce other evidence of this, but I hope it is needless to weary you with proof that our regard for the perfect repair of injuries and operation wounds is to-day altogether greater than it was twenty-five years ago, and that a new ideal of excellence possesses the minds of surgeons.

(c) My third example of the influence of this improved surgical spirit is seen in the successful efforts now made for the

radical cure of hernia. Most of us remember the time when the general opinion of surgeons was that a well-fitting truss adequately met the indications of a case of hernia. The desire to obtain a radical cure was entertained by only a few, who were held to be Quixotic and unreasonable. To-day the men who regard a truss as the proper and satisfactory treatment for hernia are the marked men, and the aim of surgeons generally is to obtain by direct operation, if need be, but anyhow to obtain, a radical cure of the deformity. This illustration of my point is so striking that by itself it would have substantiated my claim that the aim and whole ideal of surgeons are now far higher than they were twenty years ago.

(d) My fourth example of the same spirit I find in the application of surgery for the relief of many of the smaller ills and deformities to which flesh is heir. Look, for example, at the operations now performed for the relief of the various forms of talipes. I do not refer, of course, to tenotomy, which was introduced long before the period of which alone I am speaking to-night, but to the operations of tarsectomy and the like. Look, again, at the excision of varicose veins, the direct treatment of thrombosis, the excision of small moles, warts, lipomata, suspicious growths, unsightly scars, and the like. While in some of these cases graver surgical principles are also at stake, such operations are mainly undertaken in obedience to a conviction, which we all now admit to be well founded, that surgery is rightly employed in remedying the slight as well as the graver defects of structure and function. These operations are the outcome of a new spirit among us, of what I have called the higher regard for the physiological and structural integrity of the organism. They are the expression of a new idea, and if the examples I have cited appear in any case to be trivial remember that an idea is always greater than any expression it ever receives.

3. The third idea that has found expression in the recent practice of surgery is a *new conception of the real nature of a surgical operation and of the personal responsibility of the operator*. As I have already incidentally mentioned, an operation used to be regarded as in itself a potent cause of disease, and along with this was that other great misconception, that suppuration was sometimes a physiological and not always a pathological process. Surgeons used to speak of "laudable pus," "healthy pus," "healing by suppuration," and so on. These phrases are gone—gone with the false ideas connected with them. We now draw a clear and sharp distinction between the physiological process of repair and the pathological processes of inflammation and blood poisoning. When surgeons saw nearly every wound suppurate, and erysipelas, septicæmia, pyæmia, gangrene, and secondary hæmorrhage were frequent complications, and when they found that neither the surgeon's skill nor the patient's sound health, nor the use of any known dressing for the wound or of none at all, was sufficient to guard against these appalling evils, what could they think but that an operation in itself was a cause of disease? Surgeons had only too great reason for knowing that, if by an operation they might rid their patient of one diseased condition, it was, as a rule, only at the expense of setting up another and possibly a far worse malady. Those who have entered upon the study of surgery only within the last fifteen or twenty years can form no adequate conception of the paralysing effect of these facts. The surgeon's confidence in his art was sapped at its very foundation, and, what was worse, his confidence in his own power of determining the issue of his cases was destroyed. As a result surgeons were with grim irony called "brilliant" if only they could execute with despatch and dexterity the feats of the operating theatre. If a large proportion of recoveries was obtained the man was apt to be called "lucky"; if failures predominated, again it was his "luck," shoulders were shrugged, the Deity was blamed, and the surgeon took comfort in his "brilliantcy." To-day this is all a dead language to us; the very slang of the hospital theatre is gone. Instead of brilliantcy in execution only, we demand success; instead of speaking of "luck," we talk of surgical responsibility. Operations still fail, but instead of blaming the Deity we now blame ourselves for the result. For how do failures arise? (1) We may attempt what we are unable to effect, but such attempts should be made so as not to add to our patients' ills; we ought, at least, not to introduce any new elements of danger where we cannot effect relief. (2) An operation may be fatal from shock, its direct paralysing influence being more than the patient's powers can withstand. (3) Or, again, an operation may be fatal by the infliction of some injury to a really vital part, or by what is called

an accident, such as uncontrollable hæmorrhage. (4) Or an operation may be the means of infecting the patient's healthy tissues with virus introduced from without, or from within, from the patient's own tissues. So long as human nature continues what it is, with its tendency to error in observation and judgment surgeons will meet with these failures in their operations; but we cannot escape from the load of responsibility that our increased knowledge brings us, and we are bound to recognise that no one of us can any longer shield himself in cases of failure under the plea of ill-luck. As vain is it for a man to try to sever himself from his own shadow as for a surgeon to try to share in the increase of knowledge and escape from the heavier burden of responsibility it brings. And, look at the causes of failure of operations as we may, we cannot get rid of the conviction that these causes are under the control of the operator in a sense and to an extent that was never the case before. It takes but a few words to describe this great, this fundamental change that we have of late witnessed in the surgeon's estimate of the nature of his operations and of his share of responsibility in their success or failure; but no words of which I have command can adequately express the importance of the change thus indicated. The language of poetry alone is sufficient for that. Whether we regard the relief of human misery resulting from it, or the patient labours of those who have established our new position, or the marvellous world of hitherto unknown life which it has revealed, or the entire revolution of nearly all of our most firmly held pathological doctrines it has effected, the story of the germ theory of disease must long remain without any parallel in biological science.

4. Closely connected with this and arising from the same happy addition to our knowledge, surgeons have apprehended that their highest ideal is to treat directly the causes of disease. Up to the last few years surgical methods as applied to disease were crude in the extreme; they may be summarised as consisting of the removal of pathological products, as by amputation, the relief of tension, and the application of physiological rest. Knowing nothing of the ultimate causes of disease, nothing could be done to combat them. Of the many beneficent results of this change I cannot now speak; my aim is rather to fasten attention upon the change of thought itself than upon its practical outcome. I will take merely one example, and that shall be the case of tuberculous disease. For tuberculous disease of lymphatic glands the old practice never attained to anything better than the opening of abscesses, and in this it only slightly anticipated nature and in no way added to or supplemented her powers of dealing with the disease. To-day such a procedure is almost never adopted, except as a merely temporising expedient or a preliminary to a more radical operation. But, the existence of the disease being once established, the surgeon directs all his efforts to one single end—the removal, not only of the effete products of the disease, but of the active cause of the disease itself, the tubercle bacilli. As a result we have our patients well in a few days instead of their lingering on with slow suppuration for months and years, exposed all the time to a real peril of more widespread tuberculous infection. In tuberculous disease of bone we witness the same change in the treatment. It was a step in advance when excision of a tuberculous joint replaced the older plan of incision of abscesses, followed, if the case did badly, by amputation. It was a further step in advance when excision was practised at an early stage of the disease rather than late, because, the disease being more limited, the operator was the more likely to remove all the infective material. It was, however, a far more important step onward when excision was superseded by arthrectomy, the very essence of which is the early complete removal of all the diseased and infective tissue, with the preservation of all the healthy parts. From a pathological point of view, amputation and excision differ from one another only in degree; they are both of them empirical sacrifices of structures. Arthrectomy stands on a different plane altogether; it is the expression of a pathological conception—the removal of the cause of disease, and not merely its products—as well as of the physiological conception of the preservation of healthy parts. An equally striking change is seen in the treatment of chronic tuberculous abscesses—pneumæ abscesses, and the like. The old method of incision and drainage, with more or less of empirical washing out of the abscess cavity, was a grim failure. It often led to rapid death from septicæmia or pyæmia, and when it did not the suppuration continued and the abscess was said to degenerate

into a sinus. So bad were the results that many of the most experienced surgeons refused to operate at all and left the abscesses to burst, for they recognised that where they could not interfere with advantage it was their duty at least not to hasten their patient's end by an operation. It was, therefore, a great advance when Lister showed us how to open these abscesses without introducing a new element of danger by external infection of the abscess. But that, after all, only led us half the way along the path. We reached the goal only when we further learned where and what is the active cause of such abscesses and how that cause may be destroyed or removed. And so to-day we regard these cases, formerly so disastrous, as most hopeful, and yielding some of the best instances of the successful attainment of the new therapeutical ideal of surgeons—the removal of the cause of disease.

I will not weary you with further illustrations. Your own experiences will supply them in abundance. My point is that such a change in surgical treatment as this is not comparable with the replacement of one empirical method by another or of one mode of dealing with the results by another. The dealing with the actual causes of disease is a new fact in surgery, the expression of a new idea, and the conception has at one step lifted the art to a higher level, and has made it worthy of the name "scientific." Could I point to nothing else, this alone would justify my assertion that we have witnessed within the last twenty-five years such a development of the spirit of surgery, such an increased adaptation to the requirements of mankind, that "progress" is far too tame a word to apply to it; let us call it evolution.

Two collateral modes of expressing this new surgical thought are, I think, of interest to us. The first is the ardour and also the success with which the surgeon now applies himself to the arrest of morbid processes in their early stages. So long as the whole aim of the surgeon was to remove the results of disease, not to deal with its cause, he was content to wait, for mere convenience, until these products bulked large, until the case was "ripe" for treatment. But now that his object is to deal with the causes of disease he at once comes to realise that the earlier his interference the better. He is justified in this, not only by the saving it involves to the patient—a saving whether of time or of comfort, of health or of tissue—but also by its enabling him to deal more directly and more effectively with the causes of disease, because he is unfettered by the amount or the kind of the morbid results of their action. This thought has now become a firm hold upon the surgeon's mind that it has become a part of his instinct, and in any case of a failure the explanation which more readily springs to his lips than any other is that his interference was made too late. Indeed, in cases where we know nothing of the ultimate causes of the disease, as in cancer, the same principle inspires us to operate as early as the existence of the disease is recognised, and even before that, to remove "suspicious" nodules of disease, and so, if we can, to anticipate the origin of malignant growth. We do not know as an indisputable fact that the first small nodule of a malignant growth is, or contains, the cause of the disease, but we argue from analogy that it is, or does. We know quite certainly that the cause of cancer, whatever it is, does not lose its power over the individual by effluxion of time; and influenced by this, but still more by our experience in cases where the cause of disease is known to us, we endeavour to combat the evil by the free removal of the disease at the earliest possible moment. My contention is that we have no absolute scientific warrant for so doing—we soon may have it; but yet the practice is universally commended and largely followed as a result of the fact that the highest ambition of surgeons now is to remove the cause of disease, to deal with it at its fountain-head or in the germ. But we see this same tendency exerting itself in another direction—in the stimulus it gives to efforts to anticipate the graver terminations of morbid conditions. The older surgeons would quote a proverb and decline to meet evil half way, and would wait until disaster had come before they endeavoured to combat it. Such an idea is wholly foreign to surgical feeling to-day; we remove an extra-uterine gestation as soon as it is clearly diagnosed, lest it should rupture and cause a fatal hæmorrhage. If we can help it we do not wait till our patients are moribund. We excise a diseased vermiform appendix lest it should cause a suppurative local peritonitis or a fatal general peritonitis. In thus dealing with diseased conditions, not because of what they are in themselves, but to anticipate more grave accidental sequels to them that may arise, we

give expression to a new surgical thought, and the practice therefore is to be placed on a different plane in our estimation from any mere improvement in surgical therapeutics along an old line.

5. The last indication of the recent evolution of surgery that I will mention is seen in the introduction of what I will call *physiological operations* into surgery. By a "physiological operation" I mean an operation performed on a part not itself the seat of disease or known to be the cause of existing disease, but by influencing which we can affect beneficially a gross morbid change in another part. It is a kind of substitutionary surgery. There are two very closely allied instances of this class of surgical operation—the removal of the healthy ovaries in the treatment of uterine fibroma and of the healthy testicles in cases of advanced prostatic fibroma. I am not now concerned with the results of these operations or with an exact appreciation of their true value; I only want to point out that operations of this kind stand in a category by themselves, that they are the expression of a new thought, and their introduction marks a new epoch in surgery. This appeal of surgeons to some of the highest and most recondite of the laws of physiology in the pursuit of their art is a striking evidence of the new spirit by which they are influenced.

I venture to hope that I have made good my point that within the memory of all surgeons of middle age their art has been enriched by the introduction of new ideas, new aims, and a new spirit, and to such an extent has the whole thought of surgery been revolutionised that to-day the art is entitled to a totally different position in our regard from that held by it even thirty years ago. Neither the time allotted to me nor a proper sense of the demand I have already made upon your indulgence will allow of my entering at all fully upon a consideration of the causes that have led to this happy result. The gain has come to us by no lucky accident; the new light has burst upon us by no sudden inspiration; but the truth has been unfolded as we have trodden the golden pathway of knowledge. To some extent the advance, even in thought, has been gained by improvement of method, as by the introduction of anaesthesia and of better modes of hæmostasis and of new mechanical appliances. But in the main it has been as we have increased in knowledge of anatomy, of physiology, and particularly of pathology, that the change in surgical thought and purpose has been effected. Good surgery is the outcome of a sound knowledge of these three sciences. As the strength of a chain is that of its weakest link, so the most minute knowledge of anatomy, combined even with a tolerably good appreciation of physiology, failed to evolve good surgery until a knowledge of the causes of disease supplied the lacking constituent. Anatomy aids in diagnosis and guides the surgeon as to what he is to remove and how best to do it, but its only therapeutic indication is *excise*. Physiology affords indispensable aid in diagnosis, points with unerring finger to the fell results of injury and disease, but bids the surgeon hold in high regard every part and power of the living organism, and calls on him in no uncertain voice to *save* and to *preserve*. Pathology, by telling him how disease arises, lives and thrives, brings harmony out of the discord by uttering its note: *arrest, prevent*. These words may mark for us the great stages through which our art has passed. Concerning itself at first with excisions, amputations, and such coarse modes, it rose to higher things by seeing that a nobler function was preservation, not destruction. From that of late it has advanced still farther, as it has owned its chief ambition to lie in anticipating and preventing pain, disease, and death.

While in Nature evolution is seen to be the outcome of the silent working of unintelligent forces, and many refuse to accord any part to the influence of a presiding mind, in the evolution of an art all admit the predominant influence of mind and of individual genius. Were I to close this poor attempt to indicate the main course of the recent evolution of surgery and the chief forces that have led to it without any reference to that master mind to which we owe the greatest impulse that surgery has ever felt, I should be doing violence to my own feelings and to yours also. Although science knows nothing of nationality, and we here to-night rejoice in addition to our knowledge and to our powers of combating disease and death, whether it comes to us from a French Pasteur, from a Teuton Koch, from our Western cousins on the other side of the broad Atlantic, or from a son of that Eastern Empire now just rising above the horizon,

we cannot help feeling a special pride in the fact that the name that shines with an unrivalled splendour on the page of surgical history is that of the Englishman, Joseph Lister. This society is rich in traditions; the picture which hangs on our walls is a precious treasure, not alone as a work of art and the work of a great artist, but as reminding us of the very personalities of the men that were its founders and the leaders in our profession a century ago. Anticipating the future, we may be sure that it will for ever remain one of the proudest traditions of this society, that it was here, to us, that Joseph Lister made more frequent and more important communications than to any other kindred society in London. This country has been the birthplace of many of the worthiest of men in every department of life, and in the profession of medicine, to which all civilised lands have contributed so richly, we take a foremost place. But Nature is not lavish of her choicest gifts; they often come to us at what we call long intervals, as if to enable us to judge of them with a true perspective. In the seventeenth century she gave us the immortal William Harvey to lay the foundation of our physiological knowledge; in the eighteenth century she gave us John Hunter, that great biologist and profound anatomist, the founder of scientific surgery; and in the nineteenth century she enriched the race with Joseph Lister, a man worthy to rank with Harvey and Hunter, not only for his genius, his powers of observation and reflection, his patience in research, and his scientific method, but even more for the magnitude and beneficence of the results that have followed from his efforts. It is a great thing to have and to hold in reverence our mighty dead; it is a better and a greater thing still to have and to honour our mighty living. Long may this ancient society flourish! Long may she retain in her fellowship this greatest of her sons! May she ever take a leading part in the working out of those great ideas which can alone ennoble our art! And may she never lack worthy followers of him who has taken the foremost place in the Recent Evolution of Surgery!

A Lecture

ON

THE RELATION BETWEEN THE MOVEMENTS OF THE EYES AND THE MOVEMENTS OF THE HEAD.¹

Delivered before the Oxford University Junior Scientific Club at the University Museum, Oxford, on May 15th, 1895.

By A. CRUM BROWN, M.D. EDIN., F.R.S.,
PROFESSOR OF CHEMISTRY IN THE UNIVERSITY OF EDINBURGH.

WE all know that it was a long time before mankind found out that the earth moves. For ages the apparent motion of the heavenly bodies was supposed to be their real motion, the earth being fixed. We, who know something of the truth in this matter, do not, however, any more than our ancestors did, see or feel the earth move. We believe that it does so, either because we have been told by someone who, we think, knows about such things, or because we have reasoned the matter out from data observed by ourselves or reported by credible observers. But in habitual thought and speech we go back to the old assumption, which, for our practical, terrestrial purposes, answers well enough and is perfectly in accordance with our sensations. When we turn from the great cosmos to the microcosm, when we compare the motion of our own body among the various fixed (terrestrially fixed) and moving bodies around us with the motion of the earth among the stars we find quite a different state of matters. It never occurs to us that our own body is at rest and that the trees, houses, &c. move. When we really move we not only know but feel and see that we are moving, and everyone, learned or ignorant, old or young—if only he is sober—feels and sees that the solid earth is fixed, except on the rare occasion of an earthquake and in the case of some illusions which we shall have to consider. I wish to discuss the cause of this sensation of the fixedness of the earth, and

¹ Being the fourth "Robert Boyle" Lecture.

also incidentally of the exception implied in the words I have just used, "if only he is sober." If we keep our head fixed and look at any really fixed scene—say, a room in which there is nothing moving, or a landscape, if we can find one, without railway trains, ships, moving beasts, or flying birds—we can allow our eyes to run over it in as uniform or as irregular a way as we please, and see that the scene remains fixed. We might have supposed that as we move our eyes from right to left the whole scene, like a moving panorama, would seem to move from left to right, but it does not do so. It remains visibly at rest, and we know, without any reasoning about it, that the changes of view were produced by the motion of our eyes. We fancy that we can move our eyes uniformly, that by a continuous motion like that of a telescope we can move our eyes along the sky-line in the landscape or the cornice of the room, but we are wrong in this. However determinedly we try to do so, what actually happens is that our eyes move like the seconds hand of a watch—a jerk and a little pause, another jerk, and so on, only our eyes are not so regular—the jerks are sometimes of greater, sometimes of less, angular amount, and the pauses vary in duration, although, unless we make an effort, they are always short. During the jerks we practically do not see at all, so that we have before us, not a moving panorama, but a series of fixed pictures of the same fixed things, which succeed one another rapidly. It is not difficult to understand how this gives rise to a sensation of the fixedness of the external scene. If, in the otherwise fixed scene, there is a really moving object we see it move, because during the pauses, short as they are, the moving object has visibly changed its place, and in each of our fixed pictures the moving object is seen to move. If it moves too slowly for this, then we do not see it move, but only infer its motion from comparison of its position at different times. If we keep our eyes fixed on the moving object—and this is possible if it does not move too fast or too irregularly—then we see it fixed and the really fixed things moving, an illusion we have all observed when the pier seems to move and the steamer remain at rest. That the eyes jerk in the way now stated can be made plain by means of a simple experiment. If we have in the field of view a bright object, such as an incandescent electric lamp, and, after running our eyes over the scene before us shut our eyes, we see secondary images of the bright object.² Now if the eyes move continuously from one position to another, we should see between the two secondary images of the bright object corresponding to these two positions a bright band composed of an infinite number of images each infinitely near its two neighbours. But we see no such band, but a finite number of sharp individual images, each of which corresponds to the position of the eyes during a pause between jerks; unless the bright object is very bright there is nothing in the secondary image to represent the positions of the eyes during the jerk. If for a bright object we take the sun, then we do see bands joining the sharp secondary images. These bands are fainter than the sharp images and die away sooner. They are the impressions made on the retina by the image of the sun passing rapidly across it during the jerk; but if with the fixed bright object in the field we follow with our eyes a really moving thing, then on shutting the eyes we see a band of light, because the image of the bright object passed not very rapidly across the retina. This habit of jerking the eyes from one position of vision to another as fast as the light, well-poised globes can be swung round by the quick-working, straight-fibred muscles which move them may be an innate habit or it may have been acquired by our looking at things and turning quickly from one object of interest to another; at all events, it is now the way in which alone we can move them unless we fix them on a moving object.

So far I have supposed the head fixed and the eyes alone moving. Let us now attend to what happens when we move our heads.³ The movement of the head, unless it is very rapid, makes no difference at all in the phenomena just described. If we call the line along which we look during the pause between two jerks a glance-line, we may describe the whole phenomenon by saying that the glance-lines are fixed relatively to fixed external objects whether the head is rotated or not. This, of course, means that during a pause the eyes are rotated

relatively to the head about the axis on which the head is really rotated, in the opposite sense and through the same angle as the head. It might be supposed, for all that has yet been said, that this fixedness of the glance-lines when the head is rotated depends on the habit of looking at things, but that this is not the cause, or, at all events, not the only cause, is plain from the fact that the same relative movements of the eyes take place when we look at an objectless field of view, such as the clear, cloudless sky, or, as was, I believe, first noticed by Dr. Breuer, when the eyes are shut. By placing the fingers lightly over the closed eyelids we can feel the motion of the prominent cornea. If, with eyes shut and fingers so placed on the eyelids, we turn the head or turn the head and body round, we feel the eyes twitch. As the head turns round, the eyes retain for a little a fixed orientation in respect to external fixed things and then jerk so as to make up for lost time, again pause, and again jerk, and so on; so that, while the head turns uniformly, the eyes, which must of course, on the whole, make one full turn while the head makes one full turn, do their rotation intermittently, being, so to speak, left behind by the head and then making up by a rapid jerk. Another proof that these compensatory movements, as they may be called, of the eyeballs are not, or at least not wholly, caused by the effort of looking at things, is afforded by observing what happens when the head is rotated about a fore and aft axis, about an axis coinciding with a glance-line. If we keep our eyes fixed on a particular point and rotate the head about the line along which we look, we still see things fixed, the world does not seem to revolve about our fore and aft axis. Here, also, we can show by means of secondary images that we see a series of fixed pictures. If, with a bright object in the field of vision, we fix our eyes and keep them fixed on a point about 15° distant from the bright object (if we keep both eyes open, about as far from our eyes as the bright object is, so as to avoid double vision), and then rotate the head about a fore and aft axis through, say, 30° by inclining the head towards one shoulder, and shut the eyes after this performance, we see a number of sharp secondary images of the bright object arranged upon an arc of a circle the radius of which is the angular distance of the bright object from the point fixed. If I have rotated my head through about 30° I see about five secondary images, so that what I call the angle of rotatory nystagmus is, in my case, about 6°. Here we have been looking all the time at the same point, and it is not easy to suppose that the very slight attention we pay to objects seen indirectly, or, as we sometimes say, "with the tail of the eye," could lead to a habit, so fixed that we cannot escape it, of moving the eyeballs in the way described.

I have said that the movement of the head, unless it is very rapid, does not affect the fixedness of the glance-lines. Translatory motion of our body may be so rapid, as in a railway train, that the eyes cannot twitch so fast as to keep the glance-lines fixed relatively to near fixed objects. The eyes do their best; they twitch, but not enough, unless the train is moving slowly, and near objects seem to fly backwards. We succeed with fixed objects at a greater distance from us; we can see them fixed, and all objects between us and such visibly fixed objects are seen to move backwards, and fixed things beyond them seem to move forwards with us. Of course, if by keeping our attention on our carriage and its contents our glance-lines become fixed in reference to these really moving things they seem fixed, and the whole world outside of the carriage is seen to move in the direction opposite to that of our real motion. It is also obvious that rotation of the head, if it is more rapid than the quickest possible rotation of the eyeball in the head, must affect the position of a glance-line, for, in order that the glance-line may remain fixed, the eyeball must rotate in reference to the head as fast in one sense as the head rotates in reference to external things in the other sense; but in the case supposed the eyeball cannot do so. We can try this experiment without having recourse to mechanical means of rotating our body and head, which of course we can do as fast as we please, and a great deal faster than is either pleasant or safe. The most rapid rotation of our head which we are able to produce by the direct action of our muscles is what is known as "wagging"—that is, a rotation about a vertical axis upon the joint between the first two vertebrae. In this way it is possible to give the head an

² The secondary images are better seen if we look at a white surface and wink rapidly.

³ By "moving the head" I mean moving the head either alone or along with the body or any part of it.

⁴ If we take a sufficiently distant object as the thing to be looked at we may neglect the want of coincidence of the two glance-lines belonging to the two eyes, and, moreover, all that is here described is seen as well, though not so conveniently, with one eye shut.

angular velocity considerably greater than the maximum angular velocity of the eyeball. When we do this as fast as we can we see that external things do not appear steady. When we wag our head to the right we see the world wag to the left, and *vice versa*. But the external really fixed things do not appear to us to describe nearly so large an angle as the head really does; the eyes make an effort to compensate the rotation of the head—an effort only partially successful, the angle through which external things seem to move being the difference between the actual angular rate of movement of the head and the maximum possible angular rate of movement of the eyeball in its socket. This difference can best be observed—and, indeed, can be approximately measured—by observing a distant light on a dark night while we wag the head. The point of light seems drawn out into a horizontal line of light, the apparent length of which is the angular difference in question. As we can wag our head much faster than we can nod it, the apparent length of the vertical line of light into which a bright point is drawn out when we look at it and nod as rapidly as we can is much less than that of the horizontal line of light just spoken of; but I find that I can, by nodding, rotate my head about a right and left axis a little faster than I can rotate my eyes about the same axis, so that the luminous point does appear to be drawn out into a short vertical line. Such violent movements of the head occur sometimes in our ordinary (not experimental) use of our eyes, but they are rare and isolated, so that the disturbance of the fixedness of the glance-lines which they cause does not really affect our sense of the fixedness of the world. The illusion of the moving pier and fixed steamer (which we have all also observed when there is a train alongside that in which we happen to be, and we see the moving train fixed and the fixed train moving) is corrected by looking at the shore or the railway station. For a moment these also seem to move, but our glance-lines almost instantly become fixed in reference to those things which we know are fixed, and it is then difficult to recall the illusion. Another similar case is that of the moon and the clouds. We sometimes see the moon moving and the clouds fixed, sometimes the clouds moving and the moon fixed, as our glance-lines are fixed relatively to the clouds or to the moon, and a little practice enables us to change from the one sensation to the other at will.

What has been said seems to show that our immediate sense that the earth and what we call fixed objects on it are fixed is a consequence of the way in which we move our eyes, and, in particular, of the way in which, by a suitable movement of the eyeballs, we involuntarily and unconsciously compensate movements of the head, voluntary or involuntary, conscious or unconscious.⁵ That such an immediate sense of the fixedness of external fixed things is of great use to us in moving about among them is plainly shown when we observe the trouble which a drunken man, who has lost this sense, has in guiding himself.

I now turn to the question, What is the cause of this prompt and wonderfully accurate compensatory movement of the eyeballs? There are three sources from which we can obtain information leading to an answer—viz., (1) from experiments on ourselves, (2) from anatomical observations and measurements, and (3) from observations of the effects of injuries to the labyrinth of the internal ear. I shall consider these in their order.

By experiments on ourselves I mean the study of the effect on the motion of the eyes and on our sense of the fixedness of external things, of movements of our head (in this case always along with the rest of our body), which we do not make, as a rule, for any other purpose. I have already stated that if we shut our eyes, place our fingers on the eyeballs, and turn round about a vertical axis, we feel with our fingers the jerking motion of the eyeballs. If, instead of turning round once, we turn round several times—still better, if we seat ourselves on a turning-table and get someone else to turn it and us round at a uniform rate—we find that the jerks become less and less frequent, and after two or three turns cease altogether. Another thing which we observe is that, although the turn-table is being turned round at a perfectly uniform rate, we feel the rotation becoming slower and slower, and when the jerks of the eyeballs have quite ceased we feel ourselves at rest and have no sensation of rotation. Let us for convenience call the sense

in which the rotation is still going on positive. This uniform positive rotation has become to us imperceptible (as long as we keep our head in the same position in respect to the vertical) and is what we may call a "new zero of rotation." If the rate of rotation is now increased we feel this increase as a positive rotation; if it is diminished we feel the diminution as a negative rotation—a rotation the other way about. What we really perceive then is *acceleration* of rotation, using the word "acceleration" in its technical sense. If the turn-table is stopped this is a negative acceleration, and what we feel is that we are being turned round in the negative sense, and at the same time we feel our eyeballs jerk. The sense of rotation and the jerking die away in this as in the former case. If, while we are being turned round with uniform angular velocity, but after all sense of rotation and all jerking of the eyeballs have ceased, we open our eyes, we still feel ourselves quite at rest, but we see all external objects turning round us; as has been well said by Professor Mach, the external world seems to turn round inside an outer, unseen, fixed world. It is in reference to this imaginary fixed world that our glance-lines are now fixed. If the rate of rotation is changed while the eyes are open the sensation of rotation is exactly the same as if they were shut; we feel the acceleration—positive or negative—as a rotation in the one or in the other sense, and the jerks of the eyeballs take place as if the real external world were not there and we were looking beyond it at the unseen fixed world outside of it—that imaginary world in reference to which our glance-lines are now fixed. If, while the experiment I have described is going on, we move so as to change the direction in our head of the axis of rotation—for instance, if after uniform rotation about a vertical axis has gone on, with the head in its usual upright position, until the sense of rotation has ceased, we bow our head forwards so that the axis of rotation is now parallel to a line from the occiput to the chin—a very striking and somewhat alarming, but most instructive, sensation is experienced. What we feel is that we are being turned round with a rotation which is the resultant of two rotations of equal angular velocity—one the real rotation about what is now the vertical, the other the imaginary (but equally perceived) rotation in the opposite sense, about the line in the head which was vertical. If the angular movement of the head is small, so that the angle between what is the vertical and what was the vertical is small, then the two component rotations nearly neutralise one another and the strange and alarming resultant is slight; but if the head is bent so that the old and new verticals are at right angles to one another the real and imaginary components are both felt in full, and the effect is very startling. If the rate of rotation is changed simultaneously with the change of position of the head we have a resultant of two rotations of different angular velocity. The most easily observed case of this kind is when the rotation is stopped altogether at the moment of change of position of the head. Here the real component is zero and we have only the imaginary one. This is the case of the well-known practical joke. A man is asked to plant the poker before him on the floor, place his forehead on the end of it, walk round it three times, and then rise and walk to the door. The preliminary part of this experiment presents no difficulty; the victim plants the poker, puts his forehead on it, and walks round it with the greatest ease and with no sense of anything unusual; but when he rises the line in his head which was vertical is now horizontal, and he feels himself turned round about that horizontal line. The external world he also sees turning round this line, objects on the one side rising up and objects on the other side sinking down. In this visibly swaying world he has to guide his sensibly rotating body, and if his friends do not catch hold of him he is pretty sure to fall. All these experiments are most conveniently made on a smoothly working turn-table of such a size that one can comfortably lie down upon it. By the kindness of Messrs. Dove, lighthouse engineers, I had the use of a large turn-table made for the revolving lantern of a lighthouse. It could be turned round smoothly and uniformly at the moderate speed that is most suitable for experiments of the kind in question. A few experiments with such an apparatus will convince anyone that we have here to do with a perfectly definite sense and not with any vague sensations caused by the inertia of the soft parts of the body. This is one of the ways in which the phenomena have been explained by those who hesitate to believe that there can be a definite special sense only discovered within the last few

⁵ I need hardly repeat that by movements of the head I mean movements of the head whether accompanied or not by movements of the body.

years. That the origin of the sensation is not in the soft parts of the body generally, but in the head, is made perfectly plain by the fact that the position of the head and the changes of that position alone determine the sensations. We must therefore look in the head for the organ of this sense.

In close proximity to the cochlea, which is universally regarded as the organ of hearing, there is an organ of very striking and, I might say, mysterious form. It is found in all vertebrates, and occurs in them fully developed except in the lowest forms of fish. It is contained in a bony—in cartilaginous fishes in a cartilaginous—cavity which communicates in birds and mammals with the cochlea or lagena. This cavity may be divided into the vestibule and the three semicircular canals. The canals open at both ends into the vestibule, and each has at one end an enlargement called the ampulla.⁶ Within this bony case is contained a membranous structure consisting of the utricle, situated in the vestibule, and three membranous canals, each in one of the bony canals, each with an ampulla in the bony ampulla, and each opening at both ends into the utricle. The vestibule contains, besides the utricle, the saccule, a membranous bag continuous with the cochlear duct, and has in the side next the tympanic cavity a hole in the bony wall filled in by a membrane and known as the fenestra ovalis. The saccule and the utricle have each a spot on the lower wall supplied with nerves which end in air cells known as the macula acustica. The maculae acusticae are probably, as suggested by Professor Mach and Dr. Breuer, organs fitted to perceive acceleration of translatory motion, and are not connected directly with the function of the semicircular canals. The fenestra ovalis belongs to the organ of hearing, which may thus be said to have a right of way through the vestibule. We need not therefore here consider these organs any further, but confine ourselves to the semicircular canals and the utricle in its relation to them. As already stated, each bony canal contains a membranous canal. The membranous canal is, except at the ampulla, much smaller in bore than the bony canal, so that the space outside the membranous canal filled with perilymph is much greater than the space inside filled with endolymph. The membranous ampulla much more nearly fills the bony ampulla, so that here the perilymph space is comparatively small. The membranous canal is pretty firmly attached (in some animals, at all events) to the periosteum of the bony canal. (See diagram.) Each

canal is, in all animals I have examined, approximately in a plane, and it is important to consider the relations of these planes to one another and to the mesial plane of the head. As I have brought part of the apparatus with me, I may shortly describe the method I used to measure the angles which these planes make with one another, and also an improved method of which I have not yet had time to make any very full trial.⁷ It consists in attaching the preparation—either a cast of the canals, or, in the case of a bird, the dissected and cleaned bony canals—to one arm of a branched rod, and a lump of wax to the other. The rod is then fixed to the large apparatus already referred to. The canals are successively made horizontal, and a small plate of glass is fixed horizontally in each case—parallel, therefore, to each canal—to the lump of wax. We can also attach a glass plate parallel to the mesial plane. We can thus have, on a comparatively small piece of wax, glass plates parallel to all the planes the relations of which to one another are to be measured. The lump of wax is then removed from the rod, and the angles between the planes of the glass plates are measured by means of an ordinary reflexion goniometer. The general results are: 1. The canals do not lie rigorously

in planes, but sufficiently nearly so to give closely accordant results. 2. The external canals are very nearly at right angles to the mesial plane, and, therefore, from the bilateral symmetry the two external canals are very nearly in one plane. 3. The superior and posterior canals of the same side make approximately equal angles with the mesial plane. In all cases which I have examined the angle between the posterior canal and the mesial plane is somewhat larger than that between the superior canal and the mesial plane. From the bilateral symmetry, therefore, the superior canal of the one side is nearly, but not quite, parallel to the posterior canal of the other side. In the discussion of the way in which the system of canals may be supposed to act I shall for convenience assume that these canals are parallel, as the deviation from exact parallelism only complicates, but does not at all vitiate, the argument. 4. In man, and in a large number of other animals, the three canals are very nearly at right angles to one another; but in a good many of the animals I have looked at the superior and posterior canals make with one another an angle considerably greater than a right angle. Looking at the six canals as forming one system, we see that we have three axes and that at right angles to each axis there are two canals, one internal, the other external—these two canals having their ampullae at opposite ends, so that if rotation takes place about the axis, the ampulla in the one case precedes the canal and in the other follows it. The vertical axis, as we may call that at right angles to the two external (or horizontal) canals, is pretty nearly vertical in most animals in the usual position of the head when the animal looks to the horizon; in man it is not exactly so—we must bow our head a little to make this axis vertical. If we suppose that we are looking north, the other two axes are N.E. and S.W. and N.W. and S.E. respectively. In man they pass from the eye of one side to the mastoid process of the other side, and are nearly at right angles to one another. As already stated, in some animals they are inclined and are nearer the right and left than the fore and aft line in the head.

In order to see how such a system can work as a hydrodynamical instrument let us first consider one canal. Here we have two watery liquids: the endolymph within the membranous canal, its ampulla and the utricle; and the perilymph between these and the bony case. How will these behave when rotation takes place about an axis normal to the plane of the canal? The inertia of the liquids will tend to produce a flow through the canal in the sense opposite to that of the rotation. Let the rotation take place so that the ampulla precedes the canal. Here the endolymph will tend to flow from the utricle into the ampulla, and thence through the canal to the utricle again. But, as Professor Mach has pointed out, the canal has too small a bore to allow of any sensible flow through it, so that the effect of this rotation will be to increase the pressure within the membranous ampulla. But—and this is a point to which, as far as I know, no one has hitherto called attention—as there will also be a tendency of the perilymph to circulate, so in its circle there is also a narrow place—namely, at the ampulla; for as the membranous ampulla nearly fills its bony case there is not much room there for the perilymph to pass from the vestibule into the space surrounding the membranous canal. There will, therefore, be a diminution of pressure of perilymph at the ampullary end of the canal, so that the ampullary walls will be stretched by the increase of pressure within and the diminution of pressure without. Of course, when the rotation is kept up uniformly for some time the pressure inside and outside of the membranous ampulla is soon equalised and the stretching or relaxation ceases. With the cessation of the stretching the sensation must also cease. If now the rotation is stopped, the perilymph and endolymph will tend to move on, and pressure will be produced inside the membranous ampulla of that canal which during the rotation moved with the ampulla following the canal. All this will, of course, be reversed when the rotation takes place with the ampulla following the canal; the pressure inside the membranous ampulla will be diminished, that without will be increased, and the walls will become flaccid. In each membranous ampulla there is a so-called "crista acustica" where nerves terminate in hair cells, and it is not difficult to suppose that stretching of the ampullary walls will irritate these nerve endings while a relaxation of the ampullary walls will produce no irritation. If this be so, then we have three axes, each with an organ sensitive to rotation about it in either sense and capable of discriminating between the two; and as every rotation of the head can

⁶ In all animals the non-ampullary ends of the superior and the posterior canal have a common opening into the vestibule.

⁷ The method illustrated by the human skull shown is fully described, with woodcuts from photographs, in Professor McKendrick's Text-book of Physiology, vol. II., pp. 697-699, and therefore need not be reprinted here. The other method will, I hope, give more accurate measurements.

be resolved into component rotations about these three axes we have the means of perceiving the axis and what we may call the "intensity" of the rotation, or perhaps more correctly the "rotational acceleration."

This hydro-kinetic theory of the function of the semicircular canals was propounded at very nearly the same time by Professor Mach of Prague, Dr. Breuer of Vienna, and myself. I give the names in the order of publication. The views expressed by us were not exactly the same, and the statement of the theory I have just given is any one of them with additions and corrections from the other two. I have not thought it necessary to refer to the hydrostatic theory of Goltz, or, indeed, to give any details of the literature of the subject. A very full and accurate digest of almost everything that has been written on the functions of the several parts of the labyrinth of the ear has been published in Russian by Dr. Stanislaus von Stein and translated into German by Dr. C. von Krzywicki. The theory as I have just described it might perhaps have been developed, as I have here developed it, from a consideration of the structure and position of the canals; but, as a matter of fact, this was not the historical order. It was the experiments of M. Flourens that first directed attention to these organs as having something to do with the equilibrium of the body. In reference to these experiments and those made since by many able physiologists and skilled operators, I shall only say that the results seem to me to be consistent with the hydro-kinetic theory. Certain of M. de Cyon's experiments, in which he increased the pressure in the canals by inserting in them small tangle plugs without producing any nystagmus or rotatory movements of the head, appear to contradict the theory; but increase of pressure in the bony canal can have no tendency to stretch the walls of the membranous ampulla, and therefore could not be expected—if the theory as I have stated it is correct—to produce a sensation of rotation; what is required is that the pressure inside the membranous ampulla should be greater than that outside of it. The symptoms observed in cases of disease of that internal ear also appear to support this hydro-kinetic theory. But the position of the canals in close anatomical relation to the organ of hearing had impressed on the minds of physiologists so obstinate an opinion that they must be connected with the perception of sound in some way or other that even now many will not admit that they are the peripheral organs of a sense of rotation.

A favourite theory was (and there are still some who hold it) that the semicircular canals give us information as to the direction in which sound comes to us. There are two ways in which we can show that this view is erroneous: 1. By considering the physical conditions. The shortest sound wave which we can hear is so long compared with the dimension of the ear that every part of the ear must be at any instant in the same phase of the wave. We must assume that, as far as the effect of such sound waves is concerned, the liquid contents of the internal ear are incompressible. It is as absurd to speak of sound waves travelling round one of the canals as to say that it is high water at one end of a dock and low water at the other at the same time. 2. By experiments on the way in which we really do perceive the direction of sound. I shall describe two such experiments: (a) Let the observer close his eyes—for security it is best to bandage them,—seat himself in a chair, and keep his head steady. Now let an assistant produce a sharp, short sound. In showing this experiment to the Biological Section of the British Association at its meeting at Belfast in 1874 I used three coins in the way I show you now. The observer can tell with really astonishing accuracy whether the sound comes from the right or from the left, because he hears it louder in the nearer ear, but he is without any knowledge at all as to whether it comes from above or below, from the front or the back. He forms a judgment, indeed, on this point, but his judgment is usually wrong, often very ludicrously so. The experiment is most striking when the click is produced in the mesial plane of his head, in which case he has not the binaural effect to help him. In this connexion I may say that I know no experiment which illustrates so well the marvellous delicacy of our sense of relative loudness of sound, a very small deviation from the mesial plane being quite certainly recognised. We have, then, with one ear no means of ascertaining the direction of sound if we keep the head fixed. How, then, do we ascertain the direction of sound, for we all know that we can do so with very considerable accuracy? This leads me to the second experiment. (b) Let the observer,

still with eyes closed and bandaged, stand up and be at liberty to move his head. Let the assistant produce the clicking sound—not once only, but again and again at short intervals, always in the same place. The observer turns round until he faces the source of the sound. He knows that he is facing it when he hears it equally loud in both ears, and hears it to the right when he turns a little to the left, and to the left when he turns a little to the right—that is the criterion of whether the source is behind or before him. Having now got the azimuth, he seeks the altitude. Moving his head about a right and left axis he seeks the position in which he hears the sound best. He is now looking towards the source of the sound.

The concha of the external ear acts as a screen, and it is remarkable how much difference there is in the quality as well as in the loudness of most sounds with different altitudes. Stand in front of a pipe from which water is rushing and move the head round a right and left axis—bow, in fact, to the pipe—and a striking difference in the quality and loudness of the sound will be observed in the different positions of the head. It may be said that birds have no concha, and yet they perceive as well as we do the direction of sound. But there is a method by which, without any use of the action of the concha and by purely binaural observations, we can ascertain the direction of sound. By one observation, as already described, we can find a plane containing the line along which the sound reaches us. That plane is at right angles to the line joining our two ears. By moving the head we can shift the line joining our two ears, and then by another similar observation obtain the plane at right angles to the new position of the line joining the two ears and containing the direction of sound. The direction of sound is the intersection of these two planes. I do not think we use this method (although I have tried it and found it work), but we often see birds when listening incline their heads in such a way as to suggest that they use it.

There is another objection which is often brought against the theory I have been explaining. It is said, "Is it conceivable that there should be a special sense, common to man and all vertebrate animals, which has remained unknown till about twenty-two years ago? This is a sense invented, not discovered, by scientific men, otherwise we should all have known about its existence at least." This objection is not one to be met by contempt, it has a real basis; and as I believe this sense to be a real one I feel bound to look for the cause of the incredulity. A special sense is popularly understood to be a gateway of knowledge. Information as to external things comes to us in various ways, and each of these ways has from ancient time been recognised and named as a special sense; but this is not exactly the physiological way of looking at things. I may illustrate the difference by a sort of analogy. In a large business establishment the manager sits in his room upstairs. He has various ways of getting information. The post brings him letters; he looks at them—some he carefully considers and answers, others he looks at and puts into the waste-paper basket, but he has looked at them all. So we see things. Many of the things we consider, take note of; others we pay no attention to, do not an hour later remember anything about them. But there are many messages which come to the business establishment and never reach the manager's room at all; they are attended to by clerks in the office. They are not futile, they are real messages and serve their purpose, a purpose essential to the carrying on of the business. If these were not attended to downstairs the manager would very soon hear of it. So with us. There are what we may call sensory impressions which do not make their way to the conscious *ego*, but are all the same properly attended to by what in us corresponds to the clerks. If our clerks neglect their work the conscious *ego* very soon becomes aware that there is something wrong. In the case of the sense of rotation ordinarily we pay no attention to its messages; the clerks at the sensory centres of the ampullary nerves and at the motor centres of the muscles of the eyeballs do all that is necessary. We perceive the result of their work in our visual sense of the fixedness of the outside world, and we do not trouble ourselves as to how the office work has been done; but—and here I come to a matter I referred to early in this lecture—the office work is sometimes not well done, and the visual sense of the fixedness of the outside world is lost. If this is due to disease, we send for a medical man and ask him to find out what is wrong in the office and, if he can, put it right. But there is a far more common cause of the loss of the visual sense of the

fixedness of the outside world—one which it has not been left for two or three scientific men to discover in the last quarter of the nineteenth century. The most characteristic effect of alcohol is to make all reflex actions sluggish. Under the influence of a moderate dose of alcohol, what I have called the "office work" goes on all right, but not quite so fast as with no alcohol. The message arrives and the answer is sent, but not quite so promptly. The conscious *ego* may not note anything wrong, but a quantity of alcohol (far short of a dangerously poisonous dose) may delay the transmission of the signal to the muscles of the eyeball so much as to affect quite perceptibly the compensation of the movements of the head. A perfectly sober man sees the world wag a little when he wags his head very vigorously—a point of light is perceptibly drawn out into a horizontal line of light; the office work fails a little under such extreme pressure. But a little alcohol makes the office work fall more readily, and as the dose is increased it fails altogether and the sense of the fixedness of the world is wholly lost. Even in such an extreme case of intoxication, short of paralysis, the drunken man may see the world steady if only he can keep himself steady. I daresay we have all seen very drunken men walking quite straight, but with a preternatural fixedness of the head. If anything makes them move their head they totter and reel. They move the head a little; that happens to them in consequence of a small and slow rotation of the head which happens to us when we wag our head violently, and they reel and stagger just as we should reel and stagger if we tried to walk, violently wagging our heads all the time.

Just as there are blind men and deaf men, so there are men who have lost, or never had, the sense of rotation. Such persons are almost always deaf-mutes. The close anatomical relation of the organ of hearing and the organ of the sense of rotation has this effect, that imperfect development or pathological injury of the one is usually associated with similar defect in the other; and experiments on deaf-mutes have shown that a large proportion of them are defective in the sense of rotation. This is shown by the absence of the normal jerking of the eyeballs when they are rotated and by a perceptible insecurity in their gait. They do not reel as drunken men do, just as blind men find their way about much better than we could do if our eyes were bandaged; they have learned to get on fairly well with the help of experience and their other senses.

I am not sure whether, in this account of the sense of rotation, of its organ, and of the use of it, I have carried all my hearers with me and convinced you of the real existence and real practical use of this sense. I hope, however, I have made it clear that the subject is worthy of attention and that we have here matter for the careful consideration of physicists, physiologists, and psychologists.

ADENOID GROWTHS IN CHILDREN.

By EUSTACE SMITH, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN, AND TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

THE subject of adenoid growths in children is one which at the present time is exciting a great deal of attention. The subject has been often discussed, but always from the point of view of the throat specialist. It may, therefore, be not without interest to regard it from the standpoint of the general physician, and to consider the large number of derangements which may be set up by the presence in the naso-pharynx of these vegetations. The frequency with which adenoid growths are met with in children three and four years old and upwards is a matter of everyday observation, but it seems not to be so well known that they are equally common in infancy, and, indeed, that even at birth the mucous membrane in the post-nasal region may be thickened and granular from hypertrophy of adenoid tissue. At this early age the patient is rarely seen by a throat expert, and unless the child's pharynx be explored with the finger the growths will often be overlooked by the general physician, for it is perhaps exceptional for them to give rise to the ordinary symptoms of nasal obstruction. Often, even when present in quantity, there is no snoring, and the child may sleep with his lips closed, for, as Dr. Greville MacDonald has pointed out, during sleep the instinct of nasal breathing

almost always asserts itself, and even if the mouth be open at this time the tongue is drawn backwards against the palate so as to shut off this channel to the passage of air. In an infant the growths should always be suspected if the child's nose be broad at the bridge and faintly dimpled on each side at the upper border of the inferior lateral cartilages, and especially if when the chest is uncovered any retraction be noticed in the inferior region of the thorax. In childhood symmetrical retraction of the infra-mammary regions and depression of the ensiform appendix owe their origin with few exceptions to naso-pharyngeal obstruction. In marked cases, where little air enters by the nose, the nares are small and the alæ flattened, probably from disuse of the organ as an air passage. In such children other symptoms may be met with: the hard palate is exceptionally high, the tonsils are overgrown, and examination of the auditory meatus shows a deep depression of the tympanic membrane; but the symptoms first enumerated—viz., the altered shape of the nose and the retraction of the inferior regions of the thorax—are by themselves amply sufficient for diagnosis; and if any uncertainty be felt a touch with the finger will put an end to it at once. In infants who suffer from this form of nasal obstruction one of the commonest consequences is snuffling in the nose with much mucous secretion. Non-syphilitic infants who snuffle are almost always the subjects of adenoid granulations. They seem never to be free from coryza, and often sneeze violently and discharge quantities of thick mucus from the nose. With this they may be hoarse, and from the persistence of these symptoms are often suspected wrongly of inheriting a venereal taint. I have fallen into this error myself, but am now convinced that persistent snuffling in infants is no sign of syphilis in the absence of other symptoms, and even that the addition of a large spleen is not sufficient warrant for such a conclusion. It will be noticed that the appearance of the nostrils is different from that seen in a syphilitic infant. No doubt the bridge of the nose is broad, but the nares are not cracked or dry or caked with crusts; the edges are moist, and without the little linear ulcers which are so common in the inherited disease. The obstruction, too, at this age is not nearly complete, and, unlike the tainted infant, the child takes the breast with comparative ease.

A symptom sometimes present in new-born infants is a loud crowing or croaking sound which accompanies the breathing. Various names have been given to this phenomenon. It has been called "infantile respiratory spasm," "congenital stridor," &c.; but as it is not proved that spasm has any part in the mechanism of the sound a name which suggests such agency should be avoided. This congenital crowing is usually limited to inspiration, and is sometimes very loud, especially during sleep. It varies considerably in intensity at different times, and may sometimes cease temporarily, to return after a short interval. In one case which came under my notice the mother complained that often while sitting in the dining-room she could hear the noisy breathing of the child in the nursery on an upper floor of the house. This symptom, according to my later experience, is seldom unaccompanied by post-nasal obstruction. Formerly such cases used to puzzle me greatly, for, knowing nothing of adenoid growths, I did not examine for them; but since reading Dr. W. Robertson's paper¹ I have always done so, and have never failed to detect either actual vegetations or a thickened, granular state of the post-nasal mucous membrane. It is indispensable that an exploration should be made with the finger. Laryngoscopic examination is always a difficult process in young infants, and mere inspection of the larynx and its immediate neighbourhood gives little information even if successfully carried out. On the other hand, it is an easy matter to pass the finger upwards behind the soft palate, and if this be done granulations, when present, can hardly escape detection. It is only in exceptional cases, when collapse occurs in the lungs, that the stridor is associated with real dyspnoea. As a rule, in spite of the apparent labour of breathing, the child seems in no way depressed. His face is placid and shows no lividity of the lips and eyelids such as would result from imperfect aeration of the blood; nor is there hoarseness of the cry or cough, as in cases of papillomata of the larynx. The condition, however, is slow to pass away; indeed, as time goes on the croak, instead of diminishing, often grows more and more pronounced. Dr. W. Robertson attributes the stridor to bilateral paralysis of the posterior crico-arytenoid muscles

¹ Journal of Laryngology and Rhinology, October, 1891.

which expand the rima glottidis. He believes that the irritation set up by the adenoid overgrowth in the post-nasal region is transmitted to the medulla and there excites and exhausts the accessory nucleus so as to induce depraved innervation in the muscles referred to. The growing intensity of the symptoms, he thinks, can be explained by a secondary contraction of the adductors, which are no longer opposed by the paralysed muscles. However this may be, treatment should be directed to the pharynx, and if the unhealthy condition be remedied by scraping, followed by astringent and antiseptic applications, the breath sounds soon recover their normal quiet. Uncomplicated cases of this congenital crowing generally recover. The fatal cases are those in which collapse of lung has occurred. This accident is one which must always be kept in mind, for in a new-born infant it is very readily induced, and if at all extensive is most dangerous to the life of the patient.

The contraction of the chest wall in the infra-mammary region, which has already been referred to, is most commonly met with, in a child who is not the subject of rickets, after the period of actual infancy has passed. It is a consequence of collapse in the anterior part of the inferior pulmonary lobes, and if this collapse be extensive the lower part of the sternum becomes prominent from retraction of the cartilages of the ribs. But in addition to this visible shrinking of pulmonary tissue it is common to find in infants and young children who suffer from these vegetations signs of collapse at the upper parts of the lungs. There may be deficient resonance with weak, harsh breathing at the supra-spinous fossa of one side, reaching, perhaps, a short distance below the scapular spine; and this may be accompanied by a dusky tint of the lips, but without other sign of imperfect aeration of the blood. At this period of life, too, a high-pitched percussion note at the supra-spinous fossa on either side, without notable alteration of the breath sounds, is commonly due to a patch of pulmonary collapse, and is very suggestive of adenoid growths, especially if the child at the time be not troubled with cough. Often when the naso-pharynx is obstructed by a mass of this hypertrophied tissue very hollow breathing conducted from the pharynx is heard over the upper part of the chest on either side. If this be conjoined with altered percussion note from collapse of lung the combination may suggest serious disease; indeed, the mistake is common and excusable. The usual explanation of this imperfect expansion is that owing to the impediment to the passage of air through the nose, and the child's instinctive return to nasal breathing during sleep, air reaches the lungs in too small a quantity to supply all the pulmonary cells, so that some of them remain undilated. This explanation seems to me to be an inadequate one, for contraction of the chest wall must mean permanent collapse of portions of lung at the seat of retraction. But in a child with healthy lungs and normal power of expansion an intermittent reduction in the air-supply can hardly induce permanent pulmonary collapse, for the moment the want of air makes itself felt the deficiency can be made good by breathing through the mouth. Indeed, this is what actually happens. During sleep nasal breathing is carried on until discomfort is felt from imperfect aeration of the blood. The child then half wakes up, takes several deep breaths through the mouth, and immediately sleeps again. By this means all through the night any collapsed cells are being continually re-dilated; and in the daytime when respiration is almost entirely buccal the lungs will, of course, work normally. Permanent collapse of lung, when not directly induced by the blocking of a tube with a plug of mucus—and this is not now in question—must owe its origin to some agency which acts more continuously than the one referred to. This agency, it is not unreasonable to think, is nervous influence. We know that stimuli conveyed through the superior laryngeal nerve promote expiration, and that inspiration is inhibited by stimuli passing upwards through this nerve and the glossopharyngeal. Irritation continually applied to the periphery of these nerves must greatly restrict the admission of air and prevent complete dilatation of the lungs. If by this means air enters the lungs in insufficient quantity, the parts least likely to be expanded are those which lie in contact with the ribs in places where the chest wall is flexible and can yield easily to the pressure of the air outside. In infants otherwise healthy who are troubled with adenoids the recession in the infra-mammary regions and the supra-clavicular spaces may be noticed at each inspiration, and as the patients get older a permanent retraction of these parts becomes

established. But the evil effect of this incomplete expansion of lung is not limited to a change in the shape of the chest wall. Without a liberal supply of fresh air the lungs must perform their functions imperfectly; and any check to the free and active use of an organ tends to hinder its healthy development. If lungs work lazily they are apt to remain ill-developed and undersized, and small lungs are always vulnerable lungs. If, then, in such a case there be any tuberculous predisposition, the liability to the development of pulmonary phthisis is sensibly increased. The mere presence of the adenoid vegetations themselves, quite apart from their influence upon other organs, must increase this liability. A mass of lymphoid tissue of low vitality is greatly wanting in phagocytic power, and the weakened cells may not only fail to protect the system against the invasion of pathogenic micro-organisms, but, as Dr. Sims Woodhead has pointed out, may even serve as a means of carrying the bacilli from the surface to the interior of the body. The glands in connexion with the pharynx are often thus affected. In almost all cases of adenoid vegetations the cervical glands can be felt with unusual ease on each side of the neck, and it is not uncommon to find them enlarged and suppurating. In a great number—perhaps the majority—of cases of suppurating cervical glands, or of cases in which scars pointing to old abscesses are present in the neck, the cause of the secondary trouble has been adenoid growths in the naso-pharynx.

But of all the many consequences of post-nasal vegetations the influence they exert upon the nervous system is perhaps the most striking and important. There can be no question that in a neurotic child the worry set up by adenoid growths and the post-nasal catarrh they do so much to maintain is often great. One notable example of this nervous distress has already been referred to in the crowing breathing sometimes noticed in new-born infants; and, as has just been mentioned, insufficient expansion of lung may be ascribed with good reason to the same influence; but in neurotic children many other forms of nerve irritation may be traced to this source. Reflex spasm of the larynx is common with adenoid growths. Laryngismus stridulus I believe to be often dependent upon them, especially in those cases where the spasm occurs in children three or four years of age. In one such case, a child aged four years, the seizures, which had been frequent, ceased immediately the growths had been removed. In stridulous laryngitis, too, the nervous spasm is often, I think, due to this cause, and I have no doubt that the vegetations intensify the spasm of whooping-cough. Certainly children in whom the cough long retains its convulsive character, or returns after an interval of health, are almost invariably sufferers from adenoids.

The above are instances of local spasm, but the nervous distress may be distributed more widely. Attacks of general convulsions, such as come on sometimes in rickety children without apparent reason, I strongly suspect to be due to the presence of adenoids. But it is not only in young and rickety subjects that these cases are met with; growing children seven or eight years old and upwards may suffer in the same way. In these cases reflex agency may not be suspected on account of the comparatively advanced age of the patient, and the seizures may be looked upon as epileptic. But reflex convulsions are not limited to any particular age; they depend upon the sensitiveness of the nervous system, the readiness with which it responds to irritation, and the strength of the stimulus, so that convulsive seizures of a harmless nature may be seen in neurotic girls eleven or twelve years of age. In these cases the actual exciting cause is generally a post-nasal catarrh, for it is usually during a mild feverish attack, consequent upon exposure to chill, that the nervous symptoms have occurred. Other manifestations of nervous worry may also be met with. Attacks of asthma are sometimes put a stop to by removal of growths, and Dr. Greville MacDonald informs me that in at least one case he has known obstinate nocturnal incontinence of urine to cease quickly after the operation.

In children who suffer from these vegetations the hearing is often very sensibly impaired. In some cases, no doubt, this is the consequence of post-nasal catarrh and blocking of the Eustachian tube, but it is often the result of otitis, and Meyer has reported that out of 102 cases he found no less than seventy-two to be suffering from some trouble connected with the ear. It is partly on account of their deafness that so many of these children are

thought to be stupid, and there is no doubt that their faces often wear a vacant expression the silliness of which is not diminished by the mouth being held half open for purposes of respiration. But a really stupid child will often grow much more intelligent when the growths have been removed. These patients generally complain of headache, giddiness, and noises in the head. The tinnitus and perhaps the vertigo are probably dependent upon the ear mischief, but the headache, I think, is often a consequence of general weakness. It is an important fact that the majority of children who suffer from adenoids show very evident signs of defective nutrition. Sometimes they are ill-grown, and almost always their circulations are languid and their feet cold. Moreover, they are pale and thin or flabby, and although not, perhaps, physically indolent are easily tired. The common explanation of this unsatisfactory state is that, on account of the obstruction to the nose and the persistence of the patient in nasal breathing in spite of all difficulties, the lungs are ill-provided with air, so that the blood is insufficiently oxygenised and becomes loaded with carbonic acid and other impurities. But this explanation is far from conclusive. I have often been struck by the fact—of the truth of which I am convinced—that the degree of anæmia and malnutrition, and, indeed, the amount of general physical disturbance excited by the vegetations, is no just measure of the extent to which the nasal passages are obstructed; in other words, that the children whose nasopharynx is most completely blocked are by no means those whose nutritive deficiencies and nervous symptoms are the most pronounced. I believe their weakened state to be a natural consequence of the curious tendency to take cold shown by all the subjects of adenoids. They are like hot-house plants in their extreme susceptibility to trifling changes of temperature. A slight draught of air; a little too-prolonged exposure during the morning's bath; leaving the house on a raw day with cold feet, even although carefully clothed—all these are means by which chill may be incurred; and the consequent catarrh not only increases the worry in the post-nasal region and pharynx, but also invariably affects the digestive organs. These children may be said to live in a state of gastric derangement. Their stomachs are habitually out of order, and however much they eat—and often the appetite is little impaired—their food seems to do them curiously little good. The natural consequences of this chronic dyspepsia follow: the child gets thinner and paler, and suffers not only from insufficient nourishment, but also from all the discomforts and evils arising from the passage along the bowels of undigested and fermenting food. There are few children with adenoid growths who do not give evidence of some of the ill consequences which have been described. A certain amount of collapse of lung, with consequent retraction of the chest wall, may be said to be always present, and in most cases the nutrition of the child is unsatisfactory. But it is the neurotic children who suffer the most. They may not, indeed, give evidence of direct nervous irritation and spasm, but they are almost always anæmic and thin, and habitual sufferers from gastric derangement. In such children early removal of the growths is, of course, indispensable to improvement, and if nervous symptoms be present an operation is all the more urgently called for. So, also, in children of phthisical tendencies surgical measures should not be delayed, on account of the influence of the vegetations in checking nutrition and hindering the proper working of the lungs. In other cases, if the general health seems to be quite unaffected an immediate operation is not needed; but wherever adenoids are known to exist the child should, if possible, be kept under observation, so that they may be removed at any time when they seem to be doing harm. The danger of deafness alone is one which it is of the utmost importance to guard against.

Queen Anne-street, W.

THE DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The annual general meeting and congress of this society will take place at 20, Hanover-square, W., on Thursday, May 30th. The following arrangements have been made:—4 P.M., address by the President, Dr. Pye-Smith, F.R.S.; 4.30 P.M., annual general meeting, election of officers &c.; 5 P.M., paper by Dr. H. Radcliffe Crocker on the Internal Therapeutics of Psoriasis and some other Diseases of the Skin. An exhibition of living patients, drawings, microscopic specimens, &c. will take place afterwards.

THE DIAGNOSIS OF RETRO-PERITONEAL SARCOMA, WITH CASES.¹

By C. B. LOCKWOOD, F.R.C.S. ENG.,

ASSISTANT SURGEON TO ST. BARTHOLOMEW'S HOSPITAL; SURGEON TO THE GREAT NORTHERN CENTRAL HOSPITAL; AND HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANYONE who has performed many laparotomies must have met with retro-peritoneal tumours. I have twice found this embarrassing condition. In neither case was it diagnosed before the operation. Had a diagnosis been made there is no doubt but that a useless operation would have been avoided, and in one instance I should have been spared a fatality, which was a matter of much regret. I am, however, convinced that a diagnosis ought to be possible in this class of cases, and it is with special reference to this point that I propose to narrate my own experience. At the same time, others may be warned against a pitfall into which I fell and escape a similar disaster. The tumour to which I am about to refer—namely, retro-peritoneal sarcoma—is worthy of more attention than it has received. It is not mentioned in the various indices, or in the larger works upon abdominal and general surgery. So far as can be learnt no specimen of it has been shown at the Obstetrical or Pathological Societies. Hitherto the Medical Society of London has had no opportunity of discussing its peculiarities. By the expression "retro-peritoneal sarcoma" is implied a sarcomatous tumour growing behind the peritoneum and into its folds, and not connected with any of the great retro-peritoneal organs and unaccompanied with ascites. This definition excludes, therefore, sarcomata which grow from the kidney. They are retro-peritoneal, it is true, but owing to their origin they are always called sarcomata of the kidney. Similarly, one which grew from the adrenal body would be retro-peritoneal, but would be called a sarcoma of the adrenal body, and so forth. In the class of cases of which I am speaking such precision cannot be attained, because in both of the cases to which I am about to allude, and in others of the same kind, the origin of the growth was unknown. The narration of the first case will give an idea of some of the clinical and anatomical features of these retro-peritoneal growths.

CASE 1.—The patient was a robust, unmarried woman aged forty-seven years. She said she had been short of breath for nearly a year, and for three months had had a feeling of weight in the hypogastrium. Her abdomen was always big, but of late it had seemed unusually distended. Her left leg had recently become swollen. Beyond this there was nothing in her history to point to the nature of her disease. Examination showed that the abdomen was so tightly distended that the skin was shiny and the umbilicus almost obliterated. A hard tumour could be felt filling nearly the whole abdomen, but projecting most beneath the left linea semilunaris. It seemed to rise up out of the pelvis and to extend more into the left flank and upwards into the left hypochondrium than into the right side; but the rounded edge of the growth could be felt reaching beyond the umbilicus almost into the right hypochondrium and nearly into the right flank. It was said that the tumour was dull everywhere and that the area of dulness did not vary, but I doubt whether this observation was quite correct for reasons which will be given presently. There was no ascites, and no thrill could be felt or fluctuation, and nothing was heard with the stethoscope. My colleague, Dr. Remfry, said the tumour had no connexion with the uterus, and, although the signs were anomalous, thought that it might be a tumour of the left ovary. For myself, I thought that the tumour was solid and probably connected with the ovary. I opened the abdomen by the usual incision and came upon a tumour which looked and felt like a thick-walled cyst. The abdomen was so tight that the hand could not be properly introduced; but, so far as could be felt, a thick-walled cyst, with a good deal of solid growth, seemed to be in question. A trocar was thrust into the tumour, but nothing came out. I then incised what seemed to be the wall of a cyst, and scooped out a quantity of semi-solid contents. Soon some large vessels were met with, but were easily secured. By this time there was room to explore the abdomen properly, and then the left colon was found upon the surface of the tumour, lying almost beneath the left linea semilunaris. It

¹ A paper read before the Medical Society of London on May 13th, 1895.

It is probable that its attachments were a good deal injured. The suspicions which this aroused were confirmed by the discovery that the mesentery and transverse mesocolon were incorporated with the upper part of the tumour, and that the pelvic organs were free. Moreover, at the sides of the abdomen the hand could not be passed behind any part of the growth. These points were made out with much difficulty, and the growth was clearly beyond the possibility of removal. The abdomen was therefore closed in such a way as to shut off the wound in the growth from the peritoneal cavity. A drainage-tube was inserted and an antiseptic dressing applied. For the first two days the patient seemed to be progressing well; but her temperature rose, sickness and other signs of obstruction set in, and she died upon the fourth day. An examination was made, which showed that the retro-peritoneal tissue was occupied by an enormous new growth. This reached from the brim of the pelvis to the diaphragm, and had thrust its way into the root of the mesentery, into the transverse mesocolon, and towards the hilum of the spleen. It enveloped but did not infiltrate the pancreas, kidneys, and supra-renal bodies. The vena cava inferior was incorporated with its posterior surface, and the mesenteric vessels ran through its substance. The mesenteric lymphatic glands were not seen, but might have been involved in the tumour. Towards the sides of the abdomen it had reached beneath the right and left colons. From this examination it was clear that the tumour was beyond removal. The organ or tissue whence it grew was, however, left obscure, but I thought it probably originated in the retro-peritoneal tissue. Both Dr. Galloway, who made the post-mortem examination, and myself were of opinion that this growth was a myxo-sarcoma. I regret that the report of the histological examination has been mislaid, but I have a distinct remembrance that no epithelial structures were found in the sections. The physical characters of the growth were those of a sarcoma. It was yellowish-grey in colour, with a red mottling in places. It varied from a soft solid to a gelatinous consistence. It was not very vascular except where it had involved the great vessels. It did not possess any capsule, but in places its lobes had pushed the tissues before them without infiltration having occurred. No enlarged lymphatic glands could be discovered. There was no peritonitis or suppuration, but the broken-down interior of the tumour had probably become infected. Before commenting upon this case I will narrate another of the same kind which was met with last year.

CASE 2.—The patient was fifty-three years of age and had noticed a fulness and weight in her abdomen for two years. She had been married for twenty-eight years, but nothing in her history pointed to the nature of the abdominal swelling. This was considerable, for her abdomen was forty-eight inches in circumference at the umbilicus. The swelling was caused by a tumour which occupied chiefly the right side of the abdomen. It was a firm and rounded mass, dull on percussion, devoid of bruit, and projecting most beneath the right linea semilunaris. Both flanks and the right side of the abdomen were resonant, and there was no ascites. There was a zone of resonance betwixt the tumour and the liver, and its upper margin could be felt about midway betwixt the umbilicus and the right costal cartilages. Below it seemed to dip into the pelvis. My colleague, Dr. Champneys, found no obvious connexion between the tumour and any pelvic organ. He was inclined to think that it belonged to the upper part of the abdomen. He agreed that an exploratory operation was desirable. On the whole I myself thought an unusual ovarian tumour was in question. I did not understand the significance of an observation which was made a fortnight after the patient's admission. The note said on Sept. 17th that "the lump in the abdomen seems most defined both towards the mid-line and down into the flank"; and four days later the note said: "There is decided resonance now in front of the lump, extending six inches to the right of the middle line and eight inches below the sternum." When I opened the abdomen a few days afterwards such a condition was found that it is only to be wondered that the area of resonance was not more variable and irregular. There was a large solid growth behind the peritoneum, growing into the root of the mesentery and pushing the small intestines in front of it. In this process the mesentery had been partially obliterated, so that in places the intestines were distributed over the surface of the tumour, lying in grooves in its substance. The growth had lifted up the peritoneum of the iliac fossa, together with the cæcum. The tumour was probably lobulated in places; it was of the colour of fat, but rather firmer

to the touch. As the patient's condition was precarious nothing more was ascertained. The wound, which was extensive, was closed with buried silk sutures in the linea alba, and fishing gut sutures in the skin. The patient made a fair recovery, but her convalescence was retarded by an obstruction in the veins of the right leg. The iliac veins had probably been pressed upon by the tumour. I have lately endeavoured to communicate with this patient, but without success.

Remarks.—There can be no doubt whatever that had these cases been diagnosed an operation would not have been attempted. In the first the exploration forfeited the patient's life, and in the second it caused a grave and serious illness. When such a tumour as this cannot be removed at the operation the abdomen has to be closed in such a state of distension that the action of the heart and the respiration may be gravely embarrassed. In addition, every unnecessary and unsuccessful operation brings discredit upon surgery. Clearly it is of the greatest importance that we should learn to diagnose these retro-peritoneal sarcomata. In the early stages it is probable that this would not be a difficult task, especially if the abdomen was examined with the patient under the influence of an anæsthetic. The tumour would, I assume, be found to occupy some part of the centre of the abdomen near the root of the mesentery and to possess no obvious connexion with the kidneys or pelvic organs. But apparently the onset of retro-peritoneal sarcoma is so insidious that the patient is not seen during the early stages. In the cases above described the only symptoms at the beginning were breathlessness and a feeling of weight in the hypogastrium. The abdominal distension seems to have occurred so gradually that it attracted little notice. Therefore, we must reckon upon having to deal with these retro-peritoneal growths at a time when they have attained formidable dimensions and when the abdomen has become tightly distended. The difficulty of diagnosing abdominal swellings is notorious, but a solid growth which could not be attributed to any of the great organs ought, at least, to arouse suspicion. In both of the cases which I have narrated the uterus was at once excluded. The liver, too, was separated from the growth in each of them by a zone of resonance. The absence of urinary symptoms seemed to exclude the kidneys, although in one case the dulness extended into the loin. Nor could any reason be discovered for attributing the tumour to the spleen, pancreas, or supra-renal bodies. Its connexion with the ovaries was, however, in each case more difficult to decide upon and in each was strongly suspected. But not only did the tumour project into the true pelvis less than an ovarian tumour generally does, but its other characters were anomalous. Had I only suspected a retro-peritoneal growth in the first case the incision would have been prolonged and the nature of the growth revealed without putting the patient's life to an unwarrantable risk. Now, I cannot help thinking that we shall find the clue to the diagnosis of these retro-peritoneal growths in a correct appreciation of their anatomy. Let me recall what was found in the first case. In it the growth had spread behind the peritoneum and lifted up the intestines, so that the left colon ran down its front surface behind the left linea semilunaris. At the operation this part of the bowel was empty, but there must have been times when it was full of gas and capable of discovery by percussion. This information might not be obtained at one examination, but in a dubious case, such as this, no one would hesitate to defer an operation until several examinations had been made. In the second case this peculiar feature in the resonance of the tumour was actually observed, although its significance was not understood. The clinical notes said that after admission the tumour was dull on percussion; a fortnight later they said that there was a decided resonance in front of the lump, where none had been before. At the operation the appearance of this area of resonance in the front of the tumour was fully explained. The retro-peritoneal growth had extended into the mesentery, so that the small intestines were distributed over the surface of the tumour. Without question the variation in the areas of resonance was caused by one of these becoming distended. Doubtless retro-peritoneal sarcomata are rare, but others will be met with. It will be interesting to learn whether those who find them will be able to confirm my supposition that they will possess irregular areas of dulness and resonance, and, moreover, that their areas of resonance will vary from time to time.

Upper Berkeley-street, W.

TWO CASES OF INTESTINAL OBSTRUCTION.

BY P. RHYS GRIFFITHS, M.B., B.S. LOND.,
SENIOR ASSISTANT SURGEON, INFIRMARY, CARDIFF.

THE truth of Jacobsen's statement that "the advances in operative surgery have outstripped those of diagnosis in intestinal obstruction" is perhaps as strikingly exemplified in the present day as it was five years ago. To the uninitiated this may savour somewhat of a reproach upon our professional progress. It is only when one is brought face to face with practical experiences that one realises fully the formidable obstacles in the way of accurate diagnosis. Of this I am quite convinced, that there is no task in medicine or surgery where the despair of utter impotence is more often felt than in unravelling the mysteries of a case of obstruction. Turning to operative measures we find ourselves beset on all sides with difficulties. It has been truly stated¹ that "abdominal section in the treatment of intestinal obstruction, both acute and chronic, is one of the most formidable operations in surgery." According to some of the latest statistics (Curtis) a mortality of 68.9 per cent. is given in published operations since 1873 in acute obstructions. For all operations the rate of mortality would, no doubt, be much higher. Without operation Greig Smith² says that "certainly 95 per cent. die"; "the indication is clear enough—as clear as the indication to tie a bleeding carotid—operation." Treves states: "With regard to the curative treatment [of acute obstruction] the only measure is laparotomy." Immediate operation is the teaching of the progressive school. On the other hand, we have the conservative school, with its small following, crying with equal vigour for delay in operation. Hutchinson, the leader of the conservative school, perhaps the keenest observer of the present day, maintains that "these forms of strangulation are often in early stages effectually relieved without operation; that, in fact, cases of recovery without operation after very acute symptoms are not uncommon." Hutchinson "fully recognises the propriety of exploratory laparotomy in cases in which the symptoms have persisted after one or more persevering attempts at taxis under anaesthetics." Upon one point there can be no question, I think—viz., that laparotomy is the indication in all cases after the stage of established peritonitis. Two or three attempts at taxis and manipulation carried out in a "bona-fide" and energetic manner for half an hour or three-quarters upon inflamed intestines seems to me both irrational and unscientific. Unfortunately the diagnosis of the stage of established peritonitis frequently presents insuperable difficulties. Not long since, in a case of ovariectomy under my care, death, before the post-mortem examination was made, was attributed to septic peritonitis of adynamic type. Not a trace, however, of peritonitis was discovered, the patient having died from cancer of the gall-bladder. Taxis and manipulation in the early stages of obstruction may in Hutchinson's hands often relieve strangulation, but we have no evidence that they produce better results than laparotomy in the same stage. In certain cases where the obstruction is due to the presence of a foreign body this method may be commended, but on the whole it seems to me to be a blind, unscientific method in which the patient is exposed to the veriest chance operations. By the method of laparotomy, on the other hand, we endeavour by an intelligent co-operation of brain and senses (1) to discover the lesion, and (2) to remedy it. When laparotomy fails it is generally due to one of the following causes: (1) delayed interference; (2) a pathological condition irremediable from the first; and (3) inability to discover the lesion, which, by the way, is by no means an uncommon occurrence. The two following cases will serve to illustrate some of the points to which I have referred. I am indebted to Dr. A. W. Sheen, our house surgeon, for help in the preparation of the notes and the general management of the cases.

CASE 1. *Acute obstruction*.—A man aged sixty-five years was admitted into the infirmary on Jan. 15th, 1895. He had

been quite well till 4 A.M. on the 12th. He was suddenly attacked with pains in the bowels. The bowels were last open on the morning of the 12th, and during the morning he was sick. On Jan. 14th the vomited matter commenced to have a faecal odour. He had had hiccough all night for the two nights before admission and had kept nothing on his stomach. A medical man had been seeing him and had given him pills, medicine, and rectal enemas. The injections were returned at once. The patient said that he had had a rupture on the right side since he was a child. This had not troubled him for years, but he had suffered vague pains in the bowels off and on for twelve months. The rupture was put back by his medical man on Jan. 12th. The patient was a thin, ill-nourished, old man, complaining of pain and tenderness at the top of the right inguinal canal. The finger met with no obstruction in the canal. The abdomen was somewhat distended. There was no dullness anywhere. There were no visible coils of intestine. The vomited matter was stercoraceous. The pulse was fine and the tongue moist; the pupils were contracted, and the patient was very dull, being fully under the influence of opium. This was evidently a case of strangulation after reduction, probably dependent upon one of two conditions: (1) damage to returned intestine, or (2) reduction *en bloc* or *en masse*. There was no second hernia, no marked distension, nothing in the ring, and no tangible swelling in the abdominal cavity; and, feeling certain that we had to deal with a damaged intestine, the patient was sent back into the ward. During the night the vomiting persisted, and as the patient seemed worse in the morning median laparotomy was performed. A loop of small intestine lying against the internal ring was pulled out. It was six inches long and of a purplish colour; the coats were thickened and it was evidently the portion of intestine which had been confined in the hernial sac. The intestinal contents could be pushed along it. The bowel was somewhat more distended above than below. It was returned into the abdominal cavity and the wound sewn up. In the after history of the case there is very little to note. The vomiting ceased after the operation, except on two occasions. Minute doses of morphia were given to control pain. The bowels acted naturally on Jan. 20th, five days after the operation. The motions were loose and frequent, and were passed into the bed. After Jan. 30th he had one motion per diem. He was taken home by his friends on Feb. 3rd, being bodily well, but mentally very defective.

CASE 2. *Chronic obstruction*.—A man aged forty-two years was admitted into the infirmary on July 31st, 1894. He gave a history of having been ill for twelve months with "wind in the bowels, vomiting, and costiveness." He gave up work at Whitsuntide, and took to his bed on July 22nd. His bowels had not been opened since then, but he had passed a little flatus up to the morning of the day of admission. On July 28th and 31st he had "injections" without result. There was no blood or discharge from the rectum at any time. He had been retching and vomiting constantly, sick seven, eight, or nine times a day, the vomited matter being brown and watery. Latterly he had suffered from hiccough. Pain had been very bad for the last week, chiefly paroxysmal. He had got much thinner. He passed very little urine, which was bloody. Many years ago he suffered from right hip disease, which had left the limb much shortened. On admission the abdomen was found to be uniformly distended and resonant. Intestinal coils were visible. The patient complained of a constant pain with paroxysmal exacerbations, referred chiefly to the right of the umbilicus. There were no herniae; the rectum was empty. There were constant retching and vomiting, the vomited matter being watery and containing bile, but not at all faecal. He hiccoughed occasionally. He had not passed urine since admission. The patient was pale, thin, with an anxious expression and evidently of a very emotional temperament. The diagnosis was chronic partial obstruction of the small intestine. We were unable to arrive at any definite conclusion as to the pathological condition. Soon after admission a soap enema was administered, and it produced a large motion of ordinary consistence. Small quantities of milk-and-water were ordered. On Aug. 1st the patient expressed himself as being much better. He had slept in the night fairly well. The urine was acid and contained no albumen. On Aug. 2nd another enema was injected with good result. He was ordered white mixture, one ounce thrice daily. On Aug. 3rd he was sick again. The white

¹ Senn and White: Text-book of Surgery, vol. ii., p. 708.

² Abdominal Surgery, pp. 439-440.

mixture was omitted and yolk of eggs and milk, pancreatised, ordered. On Aug. 4th the sickness was worse, the vomited matter being liquid and brown, but not faecal. An enema was given with but little result. He complained of abdominal pain, paroxysmal, which he referred to the umbilicus. He sat up in bed and rubbed his stomach vigorously at intervals. He was extremely emotional; at one time he thought he was going to die, and at another wanted to get up. On Aug. 5th the patient had been constantly vomiting. The vomited matter was brown, liquid, and offensive, like the contents of the small intestine, but not stercoraceous. He was put on nutrient enemata and was given ice to suck. On Aug. 6th, at the request of the patient and after consultation with Dr. Wallace, I performed median laparotomy. Finding nothing in the common situations of obstruction, the intestine was carefully examined from a point steadily fixed by Dr. Wallace. There was distinct evidence of peritonitis, but we were unable to determine the seat of obstruction. The wound was sewn up and the patient was ordered only to have ice to suck. A quarter of a grain of morphia was injected hypodermically at 7 P.M. On Aug. 7th the patient slept for six hours. He had not been sick, but had had some pain in the abdomen. He was put on nutrient enemata, every four hours. On Aug. 8th the patient was very restless during the night. He had slight hiccough. He would not keep still, and got out of bed and took a large quantity of ice. He slept about one hour. There was no vomiting. On Aug. 9th the patient remained in much the same condition, notwithstanding the administration of sedatives. On Aug. 10th he was much quieter during the night, and slept at intervals. He had occasional abdominal pain. There was no distension of the abdomen, and no rise of temperature above 100° F. since the operation. On Aug. 11th the patient was very restless during the night. The nurse could not possibly keep him quiet. He was not sick. He had taken all his food. His bowels had not been moved since the operation until now, when from 4 P.M. till 9 P.M. they were opened thirteen times. A starch and opium enema was given. On Aug. 12th the patient was quieter on the whole; he slept two and a half hours in the night. The bowels were open seven times. He insisted on sitting up when using the bed-pan. He tried to get out of bed several times, and succeeded once, when he drank a large quantity of water. At 9 A.M. the patient was found to have several coils of intestine protruding from under the lower border of his dressing, which had not been touched since the operation. Chloroform having been administered, it was found that a suture had given way. The intestine was carefully washed, returned, and the wound resutured. The patient was much collapsed afterwards. A brandy enema was given and strychnine was injected hypodermically. On Aug. 13th the patient died at 2.35 P.M. The post-mortem examination was limited to the abdomen by request of the friends. The wound was somewhat unhealthy. There was recent peritonitis over the coils of small intestine beneath the wound. On removing the intestine an abscess cavity was opened lying between the liver, the hepatic flexure of the colon, and the duodenum. There were old peritoneal adhesions across the concavity of the hepatic flexure. The exact relationship of the abscess cavity could not be ascertained, but it seemed to originate from the hepatic flexure of the colon, the calibre of which was much narrowed, but not completely obstructed at one point. There were some clay-coloured faeces in the descending colon. There was no general peritonitis.

Remarks.—The regional diagnosis was fairly accurate. The obstruction was too near the beginning of the large intestine to permit of stercoraceous vomiting. What was the cause of the kinking of intestine and the abscess cavity? With clear evidence of old tuberculous joint mischief, a justifiable diagnosis would be tuberculous mischief of a mesenteric gland with kinking of intestine by old inflammatory adhesions. In the course of conversation with the patient he told me that he was in the habit of walking with the aid of a stick, and that he always leant forward and pressed his abdomen against his hand and stick at the point where the pain was chiefly felt—that is, in the immediate neighbourhood of the hepatic flexure of the colon. Is it not possible that this long-continued pressure may have been the cause of his abdominal trouble? May not this constant irritation have been the determining factor in establishing the tuberculous gland mischief?

Cardiff.

THE PSYCHOLOGY OF ANÆSTHESIA.

By LEONARD G. GUTHRIE, M.D. Oxon.,

M.R.C.P. Lond.,

PHYSICIAN TO OUT-PATIENTS, PADDINGTON-GREEN CHILDREN'S HOSPITAL;
PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR EPILEPSY AND
PARALYSIS, REGENT'S-PARK; AND ASSISTANT PHYSICIAN,
NORTH-WEST LONDON HOSPITAL.

IN THE LANCET of March 23rd Dr. Wyld has suggested that from the collection of psychological experiences of persons when under anæsthetics "most important facts may be arrived at as to the construction of an experimental psychology." In the annotation on the subject in the same issue doubts are expressed as to the feasibility of the suggestion, whilst the interest in the study of such dreams is admitted. I not only share these doubts, but fear that actual harm may result from the promulgation of Dr. Wyld's views. The habit of auto-intoxication by means of inhalations is already practised. Patent inhalations containing chloroform and eau de Cologne are sold to the public as cures for headache and neuralgia. Should the idea gain ground that the secrets of mental science may be divulged to those under the influence of anæsthetics inquests may soon be heard on journalists hard up for "copy" who have sought inspiration by such means. It is even conceivable that etherisation may replace hypnotism at drawing-room *soirées*; that the burning social and moral questions of the age may be discussed under chloroform instead of Chian, as at the Socratic symposium, but possibly with more disastrous results than attended the feast at the house of Agatho the Athenian. It is doubtful whether any scientific result can be obtained from the record of the hallucinations, illusions, and delusions of those under the influence of drugs beyond that which the well-known phenomena of ordinary sleep supply. Natural sleep is probably dependent on the accumulation of ptomaines—the products of digestion and exercise—in the circulation, which dull the intellectual and motor centres of the brain. Anæsthetics and other soporific drugs only differ in action from the home-brewed articles in that they produce a state of mental and sometimes bodily exaltation which precedes sleep. Profound natural sleep is dreamless, so also is the sleep of one heavily drugged. Dreams are the result of impressions both internal and external in a half-awakened brain, which distorts and exaggerates them into a seemingly connected tale. A knock at the sleeper's door weaves itself into what seems to him a lengthy series of events, yet the knock both occasions the dream and wakes him up. It is common experience that the dreamer awakes at the most exciting incident in his dream. It is not the dream which wakes him, but the impression which gave rise to it. In a dream one may be tried, condemned, tortured, executed, and buried by Inquisitors or Red Indians, and wake to find an ache or pain the cause. The distressing paralytic nightmare, in which one is pursued but cannot stir, is perhaps due to some uncomfortable posture of the legs which has caused them to "go to sleep." The clergyman dreams that he is preaching in his night-dress because he is conscious in a half-awakened state of actually wearing nothing else. Dreams under anæsthetics resemble the ordinary kind in that they are produced by partially felt impressions at the moment of awakening. A lady was once anæsthetised in my presence in order to have two teeth extracted. She came round immediately after the removal of the second wailing, "What is the use of it all?" Afterwards she explained that she had dreamed she died in great agony (tooth No. 1), that she had also been born again in equal pain (tooth No. 2), and that her remark was a protest addressed to the Deity. The whole period of extraction lasted less than twenty seconds. My own experiences illustrate the fact that dreams under anæsthetics are instigated by partially felt internal and external impressions. Once I had some post-mortem warts scraped from my hands under chloroform. I thought I was myself giving the anæsthetic whilst someone kept anxiously inquiring through a telephone, "Is he all right?" until I was in an agony of fear lest he might not be so. I thought that my hand was restrained (it was doubtless the case) whenever I attempted to give more chloroform. I heard the sound of the sharp spoon on the warts, but felt no pain, and thought they belonged to my patient. Afterwards I learned that my breathing had become embarrassed, and that the words, "Is he all right?" referred to me. The telephone was doubtless suggested by the sound of a musical rhythmical hammering

which in my case always accompanies partial anaesthesia. On another occasion, whilst under ether, I became a noble lord seated in a magnificent chariot in the "Row" at the height of the season. I was hopelessly and deplorably intoxicated, and yet became aware that an attempt was being made to photograph me in this undignified condition. I shouted to the coachman to drive on, but instead of obeying he and the footmen pressed a mask over my face. I smelt ether, and struggled madly to prevent them taking the photograph, which I thought was being done for a wager and would be all over London next day. The words "Drive on" were addressed to the operator by the anaesthetist, and doubtless suggested the dream. Such is the probable explanation of dreams under anaesthetics. If so, they are not to be distinguished from ordinary dreams, and cannot shed fresh light upon the problem of the relationship between mind and matter, as the experiences of Davey and Symonds would appear to suggest. The subjective sensation that the mind is divorced from the body, common in ordinary as well as in dreams under anaesthetics, cannot be held as an argument that such may be the case. In deep sleep the mind is practically dead; when sufficiently awakened to receive impressions it shows its dependence upon matter by acting upon the impressions received. Dreams usually occur in the waking stage of anaesthesia, or at least these are best remembered, but they doubtless also accompany the stage of excitement. The latter varies in individuals. Some give vent to peals of laughter, others wall like lost souls, and some show signs of furious rage. I have reason to believe from my own experience that this condition may be beyond measure distressing. I had ether for the first time when a second year's medical student. Some teeth were to be extracted. I was rather anxious to show that I knew too much about the process to give any trouble, and remember feeling irritated that my remarks whilst taking the ether met with no response. I said my sensations were very pleasant, whereupon the anaesthetist laughed, or I thought he did. In a moment I conceived the idea that I was being "hocussed" for some nefarious object. I was out of the chair in an instant in spite of efforts to control me, and made for the door fighting wildly round the room, shrieking for help, and, I regret to add, swearing horribly. I knew perfectly well where I was, but had wholly forgotten the purpose for which I had come. I knew the operators well, and can see their faces yet: the anaesthetist highly amused, the dentist annoyed, for I struck furiously at his face and, I believe, hit him. I was convinced

that I was fighting for my life and that they would not let me leave the room alive lest I should expose their infamous designs. Then the fit of mania, for such it was, ceased as suddenly as it began, and I submitted to be tied in the chair for fear of another outburst, which, however, did not occur. I know now what it is to have been an acute maniac, to be conscious of one's surroundings, to have the use of one's limbs, and apparently of one's senses, and yet to act on false inferences drawn from the distorted impressions of a drugged mind.

It is only natural that the dreams of the majority whilst under anaesthetics should be more spiritual than mine, for the majority of patients look upon the anaesthetist as probably their executioner and on the operating table as a likely death-bed. Yet their experiences and mine are equally valueless for the furtherance of science. The impressions of a savage running "amok," of a De Quincey who feebly excuses his vice on the ground that it exalts his higher functions, are of equal clinical interest with the dazzling visions of a dying saint or the alcoholic's snakes and vermin. All are equally true to the subjects, equally false in reality. I have seen a child who had helped herself to belladonna and glycerine, mistaking it for jam. She threw herself about the bed, now shielding her face and shrieking, "Take the great bird away!" then screaming with laughter, clapping her hands, and calling, "There's uncle down in the field by the gate; come to me, uncle!" Another child in a like condition staggered about the room, smiling, whistling, and singing snatches of songs. Most of his babble was unintelligible, but I caught the words "Hampstead Heath" several times, and he evidently imagined himself there. He pointed to a corner of the room and said, "There's a bird! No; it's a fish." Such visions, together with those of apparitions and supernatural occurrences generally, which the Psychical Society are not able to explain, are alike dependent on the working of a disordered mind. The mind, its morals, reasonings, and special senses, are dependent on the integrity of the matter which holds it. If the matter is bound or stimulated, *μανδραγόρα ἢ μέθυ ἢ τιμι ἀλλας*, so also is the mind fettered, or, it may be, unchained. To base an experimental science of psychology on the evidence of dreams, whether of the sound or unsound mind, is to start on false premisses, to appeal from Philip sober to Philip drunk, and Philip himself reversed this order of things.

Upper Berkeley-street, Portman-square.

MALARIAL FEVER AMONG WHITE MEN IN WARRI, WEST AFRICA,

From Aug. 1st, 1893, to July 31st, 1894.

By FELIX N. ROTH, M.R.C.S. ENG., L.R.C.P. LOND.,
DISTRICT MEDICAL OFFICER AT WARRI, NIGER COAST PROTECTORATE;
LATE HOUSE SURGEON, ST. MARY'S HOSPITAL, PADDINGTON.

WARRI is situated on the delta of the Niger, about 5° N. by 5° E. It lies on the bank of a river 300 yards across, forty miles from the sea, and ten feet above the sea

level. There are two tides daily, which rise and fall from four to eight feet. The following meteorological chart has been taken from my own observations and when compared with the fever table may be found interesting, showing at what time of the year the malarial fever has been most prevalent. The highest temperature registered in the sun and noticed on many occasions was 175° F.; the highest temperature in the shade was 103°; and the lowest temperature registered at night was 68°. On several occasions during the tornado season the temperature has fallen from 40° to 60° in the course of half an hour.

TYPICAL MALARIAL FEVER CHART.

On an average not more than sixteen white men are ever there at the same time during the year. I have selected for this paper seventy-two of the most severe cases of fever, as the results of these will teach more than if all the mild ones had been mentioned. I have divided the fevers into two classes—viz., (1) fever and ague, and (2) African malarial fever, which includes the intermittent and remittent types. Only one case of the former came under my observation during the twelve months, and I shall therefore only mention and describe the latter in the subjoined tables. Each patient is numbered as he came under my charge, and his age is given as well as the time he has been in West Africa and the time he has been in Warri. The number of times each patient has had fever in each month is also shown. The cases entered in the column headed "Number of years each man has been in West Africa" have generally been away from the coast every two or three years for some months.

From the time a man arrives in Warri till he leaves again he is in a chronic state of perspiration, and as long as this is going on he may be certain he is not suffering from fever. During my short experience in Warri I have found that the only treatment is to force this healthy action of the skin, and in nearly all malarial cases, when this has been proceeding, the patient has been considered out of danger.

The fever observed in Warri is remittent and intermittent. The temperature rises generally many degrees, always once daily, but in a few cases I have noticed this to happen twice during the twenty-four hours. The rise mostly takes place between 12 noon and 6 P.M., but this is not a hard-and-fast rule. The following is a typical initial stage of the fever. The patient feels dull and heavy; there is great malaise, with neuralgic pain in the head, face, and eyes; sometimes there are headache and vomiting, great pain over the region of the kidneys, liver, and spleen, as well as

over the whole of the back and down the backs of the thighs and legs; and there is often pain in all the joints. The onset is always sudden. Some patients struggle against the malaise; many give in at once and go to bed. There is often great fear of death (especially in the case of new arrivals); others become frightened when they notice the urine discoloured or when the vomiting is severe, the latter causing severe spasms over the abdominal region. The skin is dry and harsh to the touch. There is nearly always constipation, but this generally precedes the fever. In nearly every seizure that has come under my notice I have used the treatment to be presently described, and have found it absolutely successful except in the case of the patient marked No. 14 in Table II., who had been about three weeks on the coast when first attacked by fever, and was a healthy, full-blooded man twenty-one years of age. On my arrival his temperature was about 102° F. All the drugs which were considered useful were tried, but none seemed to have any effect. He took slops well, but after a few days was inclined to be despondent. This condition lasted for fully fourteen days, his temperature varying from 100° to 103°—seldom lower, but never higher—and his skin remaining harsh and dry all the time. As his condition was now becoming worse more stimulants were given. He was sponged three and four times daily with the coolest water procurable (which is not very cold in Warri), and I cheered him up to the best of my ability. This stimulating treatment was continued for several days; his temperature fell, and he was at his work again in less than a week.

The treatment observed with all the other patients was as follows. If there was much vomiting or pain, from a quarter to half a grain of morphia was given either by the mouth or hypodermically, and when this had taken effect from two and a half to five grains of calomel with colocynth and a quarter of a grain of podophyllin, together or singly, were administered. The patient being in bed, a hot-water bottle or bag was applied to his feet and another over the spleen, and he was then well covered with blankets. As soon as the stomach had settled itself (generally within half an hour after taking the morphia) from ten to fifteen grains of antipyrin were taken, followed by a large cup of weak tea. Sometimes this dose was repeated, either in consequence of being vomited or if in twenty or thirty minutes the patient did not sweat. In every case the action of the skin took place after the first or second dose. Ten-grain doses of sulphate of quinine were administered three, four, or five times daily till the patient felt symptoms of cinchonism. In some cases the antipyrin treatment had to be repeated for a day or two when the temperature rose at all and the skin refused to act well, but this seldom happened. As the temperature fell the quinine was reduced. Stimulants, unsweetened condensed milk (the climate is too deadly for cows), and meat extracts were the diet. The patient was generally at work again under a week, unless it had been a very severe case and there was much weakness. The highest temperature I have registered was 106° 8', but this is an exception; in most of my patients it has seldom risen above 105°. In a few cases delirium appeared. I have noticed it on the first or second night, but it is doubtful whether this was due to a high temperature, as it has occurred when the temperature was only from 100° to 102° 5', and one patient had delirium when his temperature was slightly subnormal. The fever runs its course in from two to thirty days, during and after which time there may be kidney, liver, and spleen complications requiring treatment according to their respective symptoms. The drugs which to me seem to have given the best results are calomel, morphia, antipyrin, and quinine. The after-treatment consists in administering arsenic, strychnia, some dilute acid, iron in its different forms, and the hypophosphites. Cod-liver oil is a most useful tonic; patients seem to take it well, and good results are obtained. Farrish's "chemical food" made up as a pill is a useful drug and is easily taken in this form.

The hot, moist climate of Warri acts injuriously on the drugs, especially on the liquid ones, and I therefore order them as solids. I have tried them in tabloid, gelatine, and palatinoid form, and prefer the last because they are easily swallowed, because they leave no disagreeable taste in the mouth, because, not being compressed, they act quickly, because they are easily dispensed, and because, when sent out in glass-stoppered bottles, they keep better than any other form of drugs in the West African climate. One drug in particular which I have had to use in so many cases—morphia quarter-grain palatinoids—was in as perfect a

condition after sixteen months on the West Coast as it was on the day it arrived.

A typical malarial fever chart is appended.

CEREBRAL TUMOUR; OPERATION; DEATH FOURTEEN HOURS LATER WITH SYMPTOMS OF IMPLICATION OF MEDULLA.

By E. N. NASON, M.B. CAMB., M.R.C.S. ENG.

A MAN aged forty-three years, while walking in the fields in July, 1894, thought he felt something in his left boot. While taking the boot off twitching began in the left heel and extended up the leg to the thigh. The twitching lasted about ten minutes. A month later he had a second similar attack, and afterwards attacks became more frequent, sometimes two occurring in one day. There was temporary paresis of the left leg after each attack, but no permanent trouble except some stiffness and a tendency to catch the toes when walking. He had no loss of consciousness and no headache, but suffered occasionally from what he called "biliousness." On one occasion, just before Christmas, the left arm became affected in a similar way, and in January, 1895, the muscles on the left side of the trunk also. The face was never affected until Feb. 2nd, on which day, while travelling by train, he had a very severe attack affecting the whole of the left side and accompanied by cyanosis and loss of consciousness lasting some minutes. It was after this attack that he first came under my care. The following conditions were then noted. On Feb. 10th there was paresis of the left leg, the extensors of the foot being most affected. There was no loss of power in the left arm or left side of the face or tongue. There was no affection of speech, no headache, and the mind was quite clear. The left knee-jerk was much exaggerated and the right perhaps more easily obtained than natural. Ankle-clonus was well marked on the left side, but was absent on the right. Plantar reflexes were present. The urine was free from albumen. There was no optic neuritis, but the retinal veins seemed fuller than natural. He denied the possibility of syphilis, but admitted a previous occasional alcoholic excess. He was put upon iodide of potassium, fifteen grains three times a day. By the end of the month there was further loss of power in the left leg; there had been several convulsive attacks, limited almost entirely to the left arm and left side of the trunk, and there was distinct paresis of the left shoulder muscles, with a feeling of clumsiness in the left hand. The grasp of the left hand, however, remained strong. Early in March he began to suffer from more or less constant headache, vertical in position, but slightly more marked on the right side. There was no area of superficial tenderness. Vision remained good, and there was no paresis of the ocular muscles, though much difficulty in fixing the eyes during examination. The pupils were equal and reacted to light. The head constantly rotated to the left while the eyes were being examined. There was slight facial paresis. On March 8th complete paralysis of the left arm was found, having come on almost suddenly. The paralysis of the left arm, now found for the first time, was absolute, while that of the leg, though of much longer duration, was not quite complete. Slight tenderness on pressure over the head on the right side of the vertex was noticed, otherwise the patient's condition remained unaltered until March 16th, when he complained of a little wheeziness and expectorated some frothy mucus. He thought he had "caught cold," but there was no other indication of catarrh. He was still taking iodide of potassium. On March 20th the patient showed signs of general cerebral compression, as indicated by mental hebetude (once), involuntary micturition, and deep, almost stertorous, breathing. The expectoration of frothy mucus still continued. There was no rise in temperature. On

¹ This may have been an indication of interference with the vagi through compression of the nuclei in the medulla.

March 21st the symptoms of general compression were much less marked. The patient discussed the question of operation rationally, and asked that something might be done at once. The right optic disc showed slight swelling not noticed before; the left remained unaltered. On March 22nd Mr. Gilbert Barling examined the patient with me, and agreed both as to the diagnosis of cerebral tumour and its locality and the advisability of operation. The patient, having been prepared the night before in the usual way, was anaesthetised with chloroform, and a horseshoe-shaped flap, including pericranium, was turned down, exposing the bone over the region of the right fissure of Rolando. After the hæmorrhage had been controlled and the flap wrapped in hot cyanide gauze, two discs of bone were removed with a 1 in. trephine. The discs were $\frac{1}{2}$ in. apart and situated on either side (horizontally) of what was judged to be a point immediately over the upper limit of the centre for the left arm. The two holes were united by Hoffmann's forceps and the opening in the bone increased by the same means till it measured 3 in. by 2 in. There was free oozing from the diploë at the anterior edge of the divided bone, but little elsewhere. This was checked by pressure with a pad of gauze. The dura mater, which looked unduly dark, bulged into the opening, felt very tense, and exhibited only a very faint pulsation. The dura mater was divided, and a flap turned up exposing the cortex, which bulged into the opening thus made and pulsed but feebly. Two large veins, much distended with dark blood, crossed the exposed cortex, and between these an incision was made which, a quarter of an inch beneath the surface, opened a large tense cyst without any definite wall. The cyst or cavity was situated immediately beneath the Rolandic area, and contained some three or more ounces of clear amber-coloured fluid, free from blood. The cavity passed deeply in the direction of the right lateral ventricle, but no solid growth or thickening could be felt. After the evacuation of the fluid the space appeared to close completely, and the pulsation of the brain became distinct. The cavity was kept free to drain itself by means of a strand of cyanide gauze; one stitch was placed in the dura mater, and the external flap replaced and fixed by silk-worm-gut sutures and the wound dressed with cyanide gauze and wood-wool wadding. The operation (at which Mr. Barling very kindly assisted) occupied one hour and six minutes, and was well borne. After being conveyed to bed the patient soon began to regain consciousness, and intimated that he wished to pass water, which he did naturally. Up to 6 P.M. he seemed to be going on very satisfactorily. The dressings had twice become saturated with cerebro-spinal fluid, and the outer portions were changed by the nurse. The pulse was steady and between 60 and 70 per minute. The respiration was 20 and natural, and the temperature 99.4° F. Quite suddenly, at 6 P.M., the character of the respirations changed, some cyanosis was noticed, and the temperature rose to 103.4° in the left and 102.2° in the right axilla. At half-past seven mucus began to collect, and the temperature rose to 105° in the left and 104° in the right axilla, and the respiration to 43 per minute. There was no vomiting or any sign of convulsion, but unconsciousness had returned. At 10 P.M. breathing became still further embarrassed, and the intercostal muscles, which had previously been inactive, suddenly began to act vigorously. The temperature had risen to just short of 106° and 105° on the left and right side respectively and the respirations to 54 per minute. There was but little change from this condition till 4.25 A.M., when the pulse, which was being taken at the time, gave a bound and stopped suddenly. The respiration continued one minute after cessation of the pulse. The temperature registered 106° and 105° after death on the left and right side respectively.

It seems probable that the course of events in this case was the following. First, the slow development of a simple cyst in the right cerebral hemisphere with increase of intracranial pressure; that this gave way into, or formed a connexion with, the right lateral ventricle on Feb 2nd, occasioning the very severe convulsive seizure accompanied by cyanosis and unconsciousness, &c.; that a communication with the ventricles subsequently existed, keeping up an increased intraventricular pressure, which was present until relieved by the operation; and that the sudden relief of pressure was followed by œdema of the centres located in the floor of the fourth ventricle, with a consequent interference with their action, leading to the fatal result recorded.

Clinical Notes: MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF INSOMNIA.

By M. CHARTERIS, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE
UNIVERSITY OF GLASGOW.

A MAN aged thirty years consulted me on Oct. 15th, 1893, suffering from insomnia. He told me that he had always been a light sleeper, but to this he paid no particular attention; but owing to an unhappy circumstance he began to suffer from sleeplessness, which grew upon him to such an extent that it had been common for him, during a period of eight months, to have no sleep for a week at a time. In the month of May, 1892, he was advised to take sulphonal, of which he took in all from thirty to forty capsules of five grains each. His condition did not improve, and, acting on medical advice, he tried, during June, July, and August, bromide of potassium every night in a dose of twenty grains, but obtained only from one to three hours' sleep. The effect of the bromide seemed to be wearing off. He discontinued its use and went to the country for ten days. During these ten days, although free from all business, he had only one night's sleep of four hours' duration, and on returning to business in the beginning of September his condition became very serious. "By this time," he stated, "my head had become strange and work was a matter of difficulty. At night my heart beat so loudly that no matter in what position I lay I could hear it. During the day I was dizzy and full of morbid fears. Something ticked in the left temple and the eyes felt hot and fiery. At the end of September I had sunk into a state of depression, and, dreading to go to bed, wandered about the streets, had lost hope and formed resolutions of which I do not like to think now, and for which I can offer no very satisfactory explanation, yet they were as real and natural as sober and sensible thoughts are to a person in good health." When I saw him he was certainly in a very depressed and morbid state of mind, but he promised to follow my injunctions. These were as follows: to take an alternative pill of mercury and podophyllum at 4 P.M. on one day and on the following night six drachms of chlorobrom at bedtime. He was requested to return at the end of a week and to bring with him notes of his case. This he did, and I found that a six-drachm dose had each night secured a sleep of five hours' duration. He continued to take this dose for five weeks, and each night had the same average amount of sleep. At the end of five weeks I considered it advisable to decrease the dose to four drachms nightly. He took this dose for four weeks, and the average amount of sleep remained the same. Then for four weeks the dose was reduced to one drachm, and with this small dose he had from five to six hours' sleep. On Jan. 19th, 1894, he saw me again, and gave me a tabulated statement of his doses for three months. This, though interesting and instructive, would be too lengthy for insertion, but it bore out completely his verbal statements. In the month of June last he called again. He was then able to secure refreshing sleep without the hypnotic and his physical and mental condition was perfect. Work was again a pleasure to him and life was worth living.

Note.—In a similar way I have treated successfully less pronounced cases of insomnia. The habit of taking the solution does not grow on the patient, and its exhibition is attended by no depression or derangements of digestion.

Glasgow.

POISONING BY EXALGINE.

By F. GRAHAM CROOKSHANK, M.R.C.S. ENG.,
L.R.C.P. LOND.

A SINGLE woman aged thirty, extremely thin, was under my care for severe asthma and consequent insomnia. On May 3rd of this year she was given by a friend, without my knowledge, five grains of exalgine. Within five minutes "she

screamed out, becoming perfectly stiff." Twenty minutes later, when I saw her, she was profoundly unconscious, her respiration being very shallow and infrequent and rapidly falling. The lips and finger-tips were markedly cyanosed and the extremities were cold; the pupils were widely dilated and fixed; the knee-jerks were absent; the pulse was 95, small and feeble. One-fifth of a grain of apomorphine was given at once, but failed to produce emesis. Free stimulation with brandy and coffee, vigorous flagellation, faradisation, and occasionally artificial respiration were employed for three hours, at the end of which time the cyanosis had nearly disappeared and respiration was fairly well established. The patient, when roused, was incoherent and failed to recognise her surroundings, rapidly relapsing into unconsciousness. About an hour afterwards there was an evident tendency to heart failure, the pulse dropping repeatedly below 50 and becoming irregular and feeble. Ether was given at regular intervals hypodermically. Nine hours after taking the drug the pulse and respiration were both good, the pupils reacted well, and the knee-jerks were present. No urine could be drawn off with a catheter. The next day the patient was perfectly well except for aphonia, which lasted for some hours. The points of interest in the case appear to be the rapidity of the onset of the toxic effects and the evident danger in giving even moderate doses of exalgin—*a respiratory poison—to asthmatics.*

LONDON HOSPITAL.

TUBERCULOUS ULCERATION OF THE BLADDER TREATED BY SUPRA-PUBIC CYSTOTOMY AND CAUTERISATION.

(Under the care of Mr. C. MANSELL MOULLIN.)

THE number of cases in which it is necessary to perform supra-pubic cystotomy for the treatment of tuberculous disease of the bladder is limited. Usually it is possible to deal satisfactorily with the condition without operation, especially by means of iodoform emulsion or perchloride of mercury and other injections, or in the female by the application of solutions of lactic acid applied through the urethra. The operation has been carried out for two conditions—(1) tuberculous disease of the mucous membrane of the bladder of unknown extent associated with signs of tubercle elsewhere; and (2) tuberculous disease occurring in the form of a single large ulcer or of several ulcers, the disease being apparently limited to the interior of the bladder, and there being no manifestations elsewhere. In the first of these groups the operation could not be expected to prove curative, yet the record of a case given by Reverdin is very encouraging; both testes and cords were affected, the prostate was diseased, and a perinephritic abscess subsequently developed. The supra-pubic fistula was difficult to close, yet at the end of two years the patient could retain urine for from one hour and a half to two hours, and passed urine which was quite clear without pain. The second group gives a better prospect of cure, but the rarity of the condition is proved by the fact that Mr. Moullin's case affords the second example only of this operation that has been published in this country since Mr. Battle's successful case in 1890. That cauterisation is not essential is evident, as the case under the care of the former surgeon, we learn, continues in good health, but it has been generally used after the cystotomy. Cases which may be added to the list of those given by Mr. Moullin are mentioned by Reverdin,¹ Ivesen (1), Schatz (1), Trendelenburg (3), Guyon (2), Poncet (1), and Roux (1). Dr. L. Bolton Bangs² has also written on the subject.

A woman twenty-two years of age was admitted into the London Hospital in January, 1894, suffering from cystitis. Her illness began three years before with an attack of hæmaturia which lasted upwards of six weeks. Apparently it was caused by lifting a heavy weight. At the same time micturition became more frequent. There was no pain, but she grew weak and ill and was unable to continue at work as a domestic servant. A few months later, after resting at home, she began to suffer from pain shooting down the right leg from the loin. Micturition became more and more frequent, until at last it took place nearly every hour. Each act was attended by intense smarting, felt chiefly at the neck of the bladder and continuing for some time after the bladder was emptied. Blood made its appearance again. The urine became foul and loaded with mucus; and for the six months previous to admission the suffering was so great that she was almost confined to bed, any attempt at walking causing intense dragging pain over the pubes. The patient was slightly built, but fairly well nourished. There was no history of previous illness of any importance. The lymphatic glands were not enlarged, the heart and lungs were normal, and there was no history of phthisis in the family. The hypogastric region was very sensitive to pressure, but there was no tenderness over the kidneys on either side. Micturition was exceedingly frequent, night and day, and was accompanied by the greatest suffering. The average amount of urine passed in twenty-four hours was only twenty-five ounces of 1015 specific gravity. It was alkaline in reaction, always contained a large amount of blood intimately mixed with it, and threw down a heavy precipitate of blood, mucus, pus, and phosphates. Microscopic examination showed the presence of tubercle bacilli upon one occasion. Benzoate of ammonia was given internally and the bladder was washed out at regular intervals with boracic acid and lactic acid, but without result. No improvement followed, and as the patient, who had been under treatment for many months, was beginning to lose weight, it was determined to explore the bladder under an anæsthetic. A number of ulcers coated over with an adherent, bloodstained, caseous deposit were found just inside the orifice. A week later supra-pubic cystotomy was performed. The sides of the bladder were held apart with sutures passed through the edges of the muscular coat; a Ferguson's speculum was introduced through the wound, and all the ulcers that were accessible were scraped and cauterised with Paquelin's canterly. Those that were situated on the anterior surface of the bladder, and which could not be reached in this way were scraped with a Volkmann's spoon, and then iodoform was thoroughly rubbed in. All the ulcers were situated near the orifice of the bladder; there were none to be seen or felt on the fundus. The lower angle of the wound was left open and a drainage-tube introduced into the bladder; the rest was sutured and dressings of sal alembroth gauze and wool applied. The tube was shortened on the third day and removed a few days later. Urine, acid in reaction, was passed naturally on the fifteenth day, and at the end of three weeks the wound was soundly healed and the patient was allowed to get up. At first there was considerable pain on micturition, but this soon wore off. Five weeks after the operation the patient passed urine four times during the day and twice at night. Six months later, when she was seen again, the frequency during the day remained the same, but she had to rise only occasionally at night. The urine was acid and contained only a little mucus, and the patient had gained flesh and strength.

Remarks by Mr. MANSELL MOULLIN.—The number of cases in which supra-pubic cystotomy and cauterisation have been performed for tuberculous disease of the bladder is not very large. Guyon³ has recorded two; Reverdin⁴ one; Battle⁵ one, in which owing to the size of the ulcer, chloride of zinc was used instead of the actual canterly; Pilcher⁶ four; and Bell⁷ three. In three cases Bardenheuer⁸ has dissected away the entire mucous membrane, practically abolishing the bladder, for very little of the lining was reproduced. In nearly every case of cauterisation the results as reported were good, and there can be little doubt that in many instances this operation might be resorted to with advantage at a much

⁸ Centralblatt für Gynäkologie, No. 14, 1894.

earlier period than it usually is. Ulceration of the bladder attended by strangury and hæmaturia is of not uncommon occurrence in young adults of both sexes; and in a large proportion of cases yields readily to local and palliative treatment. In these the ulceration is not tuberculous, or, if it is, the ulceration is very recent and involves only the most superficial layers of the mucous membrane. When the disease has lasted some time, as in the present instance, and has affected the whole thickness of the mucous membrane, and perhaps the submucous tissue as well, leaving deep ulcers coated over with a dense adherent layer of caseous debris, pus, and phosphates, the momentary application of dilute solutions of lactic acid or other drugs can be of no avail. They can never penetrate unaided through the protecting layer. In such cases the prognosis is so unfavourable, the suffering as the disease advances so intense, and the risk of supra-pubic cystotomy as it is performed at the present day so slight, that it is difficult to understand why it is not more frequently resorted to. Tuberculosis of the bladder may not be common as a primary affection. It is usually regarded as secondary to disease of the kidneys or (in males) of the genital organs. But the fact that many of the cases in which it has occurred have been women, who do not suffer in the same way from genital tuberculosis and whose kidneys were healthy, makes it rather doubtful whether in the case of men there is not a tendency to exaggerate the secondary character of the disease. The neck of the bladder is involved more frequently than the fundus, not because of the proximity of the orifices of the ureters or of the vasa deferentia, but because its blood supply is so much larger and it is so liable to attacks of congestion, and because its functional activity is so much greater.

MANCHESTER ROYAL INFIRMARY.

SECONDARY HÆMORRHAGE IN A CASE OF ACUTE PERI-OSTITIS OF THE FEMUR; LIGATION OF THE COMMON FEMORAL ARTERY; RECOVERY; REMARKS.

(Under the care of Mr. F. A. SOUTHAM.)

ACUTE periostitis usually attacks the lower end of the femur and leads to extensive necrosis unless the patient is subjected to early operation. The upper end of the femur is not often the seat of this variety of disease, and when abscess does form there may be considerable difficulty in making certain that pus has collected, for, in consequence of the thickness of the muscular covering, fluctuation is not easily felt. This case is, so far as we know, the only one of the kind in which ligation of the common femoral artery has been resorted to with success for severe secondary hæmorrhage, and is therefore of very great interest. The circulation of the limb does not appear to have been embarrassed by inflammatory swelling round the wound, which seems to have kept free from septic changes throughout. Four causes of severe secondary hæmorrhage in such cases have come under our notice in the past—viz., (1) wound of a vessel of some importance, when making the incision or counter-opening; (2) ulceration, the result of pressure of a drainage-tube; (3) softening of the wall of an artery exposed to a septic wound; and (4) ulceration as a result of pressure of a sequestrum. For the notes of this case we are indebted to Dr. W. A. Wilkinson, late house surgeon.

The patient, a boy five years of age, was admitted to the Manchester Royal Infirmary on the evening of May 10th, 1894, suffering from acute periostitis of the shaft of the femur. On examination the upper third of the left thigh was found to be the seat of a circumscribed swelling which was slightly cedematous, intensely red, and accompanied by great heat. The boy held his thigh in the flexed position. No evidence of fluctuation could be detected. The constitutional disturbance was not considerable, though during the night he was very restless, repeatedly asking for liquid, and complained of pain in the affected thigh. Lead and spirit lotion was kept constantly applied. The next day, May 11th, the inflammatory redness had disappeared; the patient seemed much more comfortable, but the swelling was slightly larger. There was no distinct fluctuation. The temperature in the morning was 100° and in the evening 102.6° F. On May 12th it was decided to explore the swelling. An incision was accordingly made, under chloroform, on the outer side of the thigh down to the bone, and forty ounces of pus were evacuated. The shaft of the femur was found to be quite bare for a considerable extent. A counter-opening was made on the inner side, and a piece of drainage-tubing was

passed from the outer to the inner opening and the cavity well syringed out with perchloride solution. On May 13th the temperature in the morning was 98° and in the evening 100°. On syringing the cavity with perchloride solution there was a slight discharge of laudable pus. On May 14th the temperature in the morning was 98.8° and in the evening 102.6°. The cavity was syringed again. On May 15th, at 2.30 A.M., it was found that hæmorrhage had occurred, the whole of the dressings and the bed being saturated with blood. The bleeding was very profuse and came from both openings. An Esmarch's tourniquet was applied to the limb, and, the bleeding having been arrested, the tube was removed, and both wounds were freed from clots and packed tightly with iodoform gauze. Pressure with pads was applied, and the whole limb bandaged from the foot upwards and placed in a raised position. The tourniquet was then taken off. The patient was much collapsed, with a rapid, feeble, and fluttering pulse, shallow and sighing respiration, and great blanching of the skin and mucous surfaces. The usual treatment was adopted—viz., the head was kept low, hot bottles were applied, and fluid nourishment was given in small quantities. From May 15th to June 2nd all went well, and no further hæmorrhage took place. The wound had been dressed daily, the discharge gradually diminishing, and the sinuses appeared to be granulating up. The condition of the patient was also very much improved. However, on June 3rd he had another very severe attack of hæmorrhage, which recurred on the 5th and on the 7th. On each occasion pressure had to be applied to the femoral artery, and the sinuses freed from clots and packed with iodoform gauze. The boy's condition was now worse than before, and as consent for amputation was refused, and it appeared probable that any further recurrence of the hæmorrhage would rapidly prove fatal, it was resolved to enlarge the openings and if possible secure the bleeding vessel; and, failing this, to proceed at once to ligature the common femoral artery, this vessel being selected as it was difficult to determine whether the bleeding came from the superficial femoral or branches of the profunda arteries. On June 8th the sinuses were laid freely open and scraped with a Volkmann's spoon. An attempt to find the source of the hæmorrhage proving unsuccessful on account of the sloughy condition of the soft parts round the bone, the common femoral artery was forthwith ligatured, the sinuses being packed as before with iodoform gauze. After this date there was no further hæmorrhage, the circulation in the limb was perfect, the ligature wound healed by primary union, and on Aug. 6th the sinuses had completely closed. A rather troublesome complication was a contracture of the knee, but this was overcome by extension and the use of a splint, and when on Aug. 13th the limb was placed in a plaster-of-Paris bandage it was quite straight. On Aug. 22nd the boy was sent to the convalescent hospital, where he entirely recovered from the effects of the hæmorrhage and put on flesh rapidly.

Remarks by Dr. WILKINSON.—The interest in this case attaches itself not so much to the complete recovery of the bone after the periostitis, but to the success which followed the ligation of the common femoral artery after several severe attacks of secondary hæmorrhage. It will be seen that the patient had four separate attacks—the first on the third day after the initial operation, the second on the twenty-fourth, the third on the twenty-fifth, and the fourth on the twenty-eighth day after the operation, so that there was an interval of three weeks between the first two attacks, during which time the discharge was very slight and serous in character. The source of the bleeding could not be made out satisfactorily, though from its character, which was more a welling up in a continuous stream than a jetting and forcible stream, it resembled bleeding from the distal end of a cut artery. Whether this was so or not cannot be said, for when the femoral was tied the bleeding had stopped, and though the sinuses were explored the tissues were found in such a sloughy condition that nothing definite could be made out as regards its origin. With regard to the cause of the hæmorrhage, one cannot account for it in any other way than as the result of the spread of septic inflammation from the diseased bone to the walls of the bloodvessel, though the drainage was perfect. It certainly cannot have been due to any disease of the vessel wall, and none of the constitutional conditions that predispose to hæmorrhage were present. The case demonstrates the fact that ligation of the artery higher up has its place in the treatment of secondary hæmorrhage, though it is not successful in the majority of cases, as is shown by statistics. It must, however, be admitted that in cases like the above this treatment is worth a trial before

resorting to the more heroic measure of amputation. One other point of interest in the case is the fact that, considering the unhealthy condition of the tissues and the weakened state of the patient, the vitality of the limb was maintained after ligation of the common femoral artery, statistics showing that a common result of this operation is gangrene of the lower extremity, as the ligature is applied above the origin of both the great nutrient arteries of the limb.

GENERAL INFIRMARY, LEEDS.

A CASE OF NECROSIS OF THE TIBIA OF EIGHT YEARS' DURATION, WITH LENGTHENING OF THE AFFECTED BONE AND THE FIBULA OF THE SAME SIDE;
REMARKS.

(Under the care of Mr. W. H. BROWN.)

THE condition of overgrowth of one of the long bones after necrosis of the shaft is not unusual; for instance, in the Leipzig Clinic, in 28 per cent. of the cases of

which acts as a kind of bow-string. The example of altered growth illustrated below is unusual, as the fibula does not appear to have been affected by the inflammatory process. The only explanation that appears quite adequate to account for it is that the vessels of the fibular side of the limb were increased in number, as were those on the tibial side, in consequence of the acute inflammation of the tibia, and that a state of chronic hyperæmia was produced, which resulted in hypertrophy of the bone; but why they became thus affected is not apparent. For the following notes we are indebted to Mr. Douglas Seston, house surgeon.

The patient, a boy aged fifteen, was admitted to the General Infirmary, Leeds, on Oct. 25th, 1894. Eight years previously he suddenly awoke one morning suffering from severe pain in his right leg; on attempting to walk he suffered very great pain; he was compelled to remain in bed for six weeks, during which time the leg became considerably swollen. At last the skin gave way, and there was a free discharge of pus. There was no history of any

FIG. 1.

View showing position of sinus in tibia and lengthening of right leg. necrosis of the femur elongation followed. We commonly see it also in the tibia, the bone assuming a bent shape from the want of corresponding growth of the fibula,

FIG. 2.

Back view showing lateral spinal curvature. previous illness or of traumatism. Since this time there had been a discharge from the sinus, and on few separate occasions small pieces of dead bone had been

removed. About four years ago the patient first noticed that the right leg was longer than the left; the difference between the length of the two legs at that time was said to be half an inch. This lengthening had become gradually more marked. He had never suffered from any pain or difficulty in walking since the first illness. At the time of his admission to the infirmary the patient was a healthy, intelligent boy fairly well nourished; he walked with a slight limp, but had no pain at all. The right tibia was thickened throughout the whole extent of the shaft. About the middle there was a sinus through which a sharp piece of necrosed bone half an inch in length protruded. On measuring the right tibia it was found to be two inches longer than the left; the right fibula was lengthened to the same extent. There was no distortion of the ankle-joint. There was a well-marked lateral curvature of the spine, the convexity being to the right above and to the left below. On Oct. 29th, under ether, sequestrotomy was performed, and a piece of necrosed bone two and a half inches long was removed from the interior of the shaft of the tibia. The wound gradually filled up, and the boy was sent home on Nov. 17th with a small superficial wound.

Remarks by Mr. BROWN—I have not hitherto observed any such condition as described in the foregoing notes. The text-books mention the abnormal growth of bones after long-standing inflammation, but fail to explain, why, as in the present case, a neighbouring healthy bone should undergo a similar increase in length. I have seen several cases where the overgrowth after necrosis has resulted in luxation of the joint of which the affected bone forms a part. If in the case under notice the fibula had not increased equally with the tibia a disabling distortion of the ankle-joint must have resulted. I have not come across any suggestion of treatment to obviate or modify this deformity, which of necessity will be well in progress before it is noticed. Any interference locally would probably aggravate the condition by setting up fresh inflammatory action and hence favouring further growth. The engravings (which are taken from photographs) show the patient's present condition.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Absorption and Metabolism in a Case of Pancreatic Obstruction.—Observations and Experiments on the Pathology of Graves' Disease.—The Relation of Swine Fever to General Ulcerative Colitis.—Imperforate Duodenum.—Actinomycosis of Cheek.—Malignant Reversion of Cystic Fibromata.—Diphtheria and Pseudo-diphtheria Bacilli from two sisters simultaneously affected.—Cultural Variations of Streptococcus Pyogenes.

THE last ordinary meeting of the present session was held on May 21st, the President, Dr. PAVY, being in the chair.

Dr. VAUGHAN HARLEY read a paper on Absorption and Metabolism in Obstruction to the Pancreatic Duct. After first relating the changes which occurred in the absorption of food in animals after partial or total extirpation of the pancreas, he proceeded to give the results of analysis in the case of a boy aged thirteen who apparently suffered from pancreatic obstruction due to gastritis following scarlet fever. Through the kindness of Dr. Auld of Wimborne he had the opportunity of making these analyses while the boy was on a fixed diet. In a series of analyses sugar never appeared in the urine, neither did acetone or aceto-acetic acid, so that it was evident that the obstruction of the pancreatic duct had led to no destruction of gland tissue. The bile passages had remained free, as there was neither jaundice nor bile in the urine, and bile products were found in the faeces. The boy was placed for four days on an exclusive diet of milk, all medicines having been stopped. A healthy individual when fed entirely on milk passed per diem with the stools about 1.5 grammes, or 7.7 per cent., of the nitrogen given. In the case of the boy fed on the same diet he passed in his stools 5.25 grammes, or 40 per cent., of the nitrogen given. It was found that drgs passed in their faeces very much the same percentage, so that in a boy with probable pancreatic

obstruction absorption of proteids from the intestines was very much hindered. As regarded the fats, while the normal man on milk diet passed about 6.7 grammes—that is to say, 5.6 per cent. of the quantity given—the boy with pancreatic obstruction passed no less than 143.80 grammes per diem—that is to say, 73.05 per cent. of the quantity given. It was thus very apparent that the absorption of both proteids and fat was influenced when the pancreatic juice was hindered from reaching the intestines. Carbohydrates were also somewhat interfered with, as pointed out by Abelmänn. As regarded body weight, the boy's weight on ordinary diet was 84 lb., during the second day on milk diet it was 83½ lb., and on the third and fourth days on milk diet it remained 83 lb. On returning to ordinary diet he regained his original weight. In the milk diet he was given no less than 2983.83 calories per diem—that is, 78.9 calories per kilo. When one subtracts from this the quantity of calories which were lost in the stools we find the boy absorbed 1336.8 calories—that is, no less than 36 calories per kilo. It would thus appear that in this case of probable obstruction to the pancreatic duct not only was the absorption of food from the intestines greatly interfered with, but even the food which had been absorbed from the intestines was not properly assimilated. Otherwise we could not explain the fact that a healthy individual when not doing excessive muscular exercise might retain his body weight on about 30 calories per kilo, while this boy, even when he absorbed 36 calories per kilo, was unable to retain his body weight. The diagnosis was confirmed by the fact that when the boy was given raw pancreas the fat in the stools was very greatly diminished. Another interesting point which Dr. Vaughan Harley's analysis brought out was the fact that, both in animals and man, when the pancreatic juice was prevented from reaching the intestines, the fats in their passage along the alimentary canal were nevertheless broken up, not only into free fatty acids and glycerine, but formed soaps—the only difference between the condition in health and that in obstruction to the pancreatic duct apparently being that a slightly increased quantity of soaps was eliminated with the faeces. It would appear from this analysis that although the pancreatic juice was more or less essential for the purpose of absorption of fat from the intestines, it did not owe this power to the "fat splitting-up ferment" of Claude Bernard, and therefore the non-absorption of fat in these cases was as yet unexplained. In conclusion, he gave as a summary the results of analysis in dogs and man. In cases of obstruction of the pancreatic flow the fat absorption in man was diminished to 26.95 per cent., while in the case of dogs with partial removal of the pancreas 4 to 37 per cent. of the fat given was absorbed. Still further, in the case of dogs in which the pancreas had been entirely removed no fats whatsoever were absorbed in the space of seven hours. As regards the proteids, 22 to 53 per cent. of the proteids given were absorbed in dogs; while when the animal had considerably lost flesh only 17 per cent. were absorbed. In the boy's case 60 per cent. of the proteids given were absorbed. Further, the body weight was unable to be kept constant when the individual absorbed the normal quantity of calories.—Dr. HERRINGHAM asked if there was evidence that the pancreatic duct was really obstructed.—Mr. RUSSELL WELLS asked what first directed attention to the fact that the boy was out of health.—Dr. VAUGHAN HARLEY, in reply, said that the symptoms were extreme weakness combined with the passage of most offensive stools, in which free fat floated.

Mr. W. EDMUNDS brought forward some Observations and Experiments on the Pathology of Graves' Disease. He came to the following conclusions. Accessory thyroids were extremely active functionally and were not merely embryonic. The symptoms of Graves' disease were due to some form of nerve disease rather than to a secretion from the diseased thyroid because (a) thyroid feeding or thyroid extract would not cause exophthalmos, (b) but the eye symptoms could be produced by stimulation of the cervical sympathetic and were therefore certainly of nervous origin. The enlargement of the thyroid could be explained by stimulation of the sympathetic. All the symptoms of Graves' disease could be produced by an artificial lesion of the brain, and all the symptoms, including the enlarged thyroid, could be produced temporarily by mental emotion. It was suggested that in cases in which ulceration of the cornea was threatened the sympathetic in the neck should be divided.

Mr. LEOPOLD HUDSON exhibited a series of Recent Specimens of the Large Intestine of Pigs which were affected with Swine Fever to illustrate the similarity of distribution between these lesions and the condition in the human being which had been described as simple or general ulcerative colitis. The specimens were obtained from the Board of Agriculture, whither they had been sent for the inspection of the Scientific Committee on Swine Fever at present sitting. This committee had been appointed to review the experience gained since the Swine Fever Act of 1893 came into force respecting the etiology, pathology, and morbid anatomy of the diseases classed as swine fever, and to supplement that experience by a series of experiments as to the bacteriology and life-history of these diseases, and as to their communication either directly or indirectly from animal to animal. In regard to this latter point Mr. Hudson raised the question whether this disease was communicable from swine to mankind. In the specimens shown the ulceration was confined to the caecal aspect of the ileo-caecal valve and to the large intestine, and every stage could be found, from the small simple ulcer to the large confluent areas of destroyed mucous membrane with adherent masses of necrotic tissue. In the human being the distribution of the ulceration was similar, though the naked-eye appearances were different owing to differences in gland structure in the human and pig's intestine respectively. With regard to clinical symptoms it was shown that in the pig the disease assumed either an acute or a chronic form, the acute disease being accompanied by fever and producing a rapidly fatal result, while in the chronic form the pig at first showed but little signs of illness, the temperature being often subnormal; then later diarrhoea and marasmus occurred. In the human being ulcerative colitis likewise presented either an acute or chronic form. Examples of the acute affection had been recorded in the Transactions of the Society by Dr. Allchin, Dr. Sharkey, and others, the disease being accompanied by fever of an irregular type and by the passage of blood and occasionally of sloughs by the bowel. In the chronic form, on the other hand, the temperature was often subnormal; the main symptoms were the progressive emaciation and diarrhoea. With regard to bacteriology there was already, in the case of the pig, an extensive literature; but in the case of ulcerative colitis in the human being but little had at present been accomplished. It was remarkable that in Dr. Allchin's case the patient herself attributed her illness to the eating of pork; the disease was also frequent in asylums, the patients of which institutions were frequently fed largely on pork. These facts, as well as the similarity between the disease in swine and in mankind both as to morbid anatomy and described clinical symptoms, certainly seemed to justify the prosecution of further inquiries as to their possible intercommunicability.—Dr. KANTHACK remarked that in cases of ulcerative colitis in the human being the lesions had been attributed to the action of the bacillus coli communis.—Dr. ROLLESTON said that the specimens shown did not seem to resemble the cases of ulcerative colitis he had seen in the human subject, in that in the latter large areas of necrosis did not occur, and he thought that in the swine there was not such a tendency to perforation.—Dr. HERRINGHAM said that in some cases in human beings necrosis occurred; for in one of Dr. Tooth's cases sloughs were passed, and the same occurred in one of the cases Dr. Hale White had related.—Dr. HALE WHITE said that the variations between individual cases were so great that it was very difficult to attempt to draw conclusions from the morbid anatomy alone.—Dr. VOELCKER said that in a case of ulcerative colitis which he had examined there were large patches of acute necrosis of the mucous membrane. The ulcers in the swine appeared to him to be more discrete than in the human subject.—Professor COPPE, Chief Veterinary Officer to the Board of Agriculture, gave a description of the onset and progress of the disease in swine. He said that in an early case all that would be found were small hyperaemic spots in the mucous membrane of the intestine; after that infiltration took place and a central area of necrosis formed. The ulcers might remain discrete and isolated, but very commonly they became confluent. The disease was extremely fatal to young animals, often before the ulceration had started. Two common pathological varieties of the disease were met with—the ulcerative and the diphtheritic form. Two good instances of the latter variety were shown.—Mr. HUDSON, in reply, remarked that the specimens shown were mostly of the chronic form of the disease; the acute form was now not so commonly met with

owing to the regulations in force for the destruction of affected animals and all pigs in contact with them. But the acute form, with its extensive confluent ulceration and with but little adherent slough, resembled very closely the disease as seen in the human subject. Experiments were about to be performed by inoculating and feeding pigs with ulcerative colitis from human beings, with a view to discover if intestinal lesions could be thereby produced. The colon of the pig contained a number of glands precisely like Brunner's glands in the human duodenum, and ulceration and infiltration of these produced the peculiar "button" ulcers of swine fever.

Mr. A. T. COLLUM exhibited a specimen of Imperforate Duodenum.

Mr. H. J. WABING showed a specimen of Actinomycosis of the Cheek. In the majority of cases this rare affection was consequent upon a disease of the upper or lower jaw, usually the latter. The patient was a young, healthy looking man aged twenty years, who came to hospital on account of a swelling of the left cheek. He first noticed the swelling in November, 1894, after which date it gradually increased in size, and in the middle of December it burst into the mouth, a certain amount of purulent fluid being discharged. After this the swelling for the most part disappeared, but in January, 1895, it reappeared, and till he came under observation it gradually increased in size. When seen the patient presented upon the left cheek a hard, irregularly shaped swelling about the size of a half-crown piece. This involved the whole thickness of the cheek, and upon the internal aspect there were several small fluctuating spots where the swelling had broken down. One of these was incised and a small quantity of purulent fluid evacuated. This was collected, and in it were found a number of small oval-shaped bodies which had a whitish colour. These were examined by Dr. Kanthack, who demonstrated the presence of the actinomycotic fungus. The patient was admitted to the hospital and the following operation performed. The reddened area of skin over the swelling was removed by an elliptical incision and the underlying tissues, which were infiltrated by the inflammatory process, were thoroughly scraped away with a Volkmann's spoon. The mucous membrane of the mouth was not divided as the swelling lay over the course of the parotid duct. After this had been done the wound was irrigated, and then packed with iodoform gauze upon which had been spread a layer of iodoform paste. This method of dressing was repeated daily, and at the expiration of three weeks the cheek was quite healed. There were several enlarged submaxillary and parotid lymphatic glands, but these were thought to be due to simple inflammation, and on this account they were not interfered with. The swelling of these glands soon cleared up after the operation. This case was of interest on account of its rarity and also on account of the result of the treatment. It could not be ascertained how the patient had contracted his disease; in all probability the inoculation must have taken place on the inner surface of the cheek; possibly the fungus may have been introduced along with some infected food. The presence of iodoform in the wound appeared to have a considerable influence in arresting the growth or destroying the life of the fungus.

Mr. HERBERT SNOW read a paper on the Malignant Reversion of Mammary Cystic Fibroma. Case 1 (*reversion into carcinoma*).—The patient, aged sixty-four years, had the left breast excised in February, 1887, for a tumour as large as an orange, of several years' duration; there was no gland enlargement. The mass consisted of firm, white fibrous tissue studded with minute acinous dilatations, lined by columnar epithelium; there was nowhere any trace of carcinoma. In March, 1888, there were extensive deposits in the scar, in the corresponding axilla, and in the viscera, which were found post mortem to be infiltrated with typical scirrhus carcinoma. Case 2 (*reversion into true sarcoma*).—In April, 1893, a patient aged forty-two years had her right breast excised for a bossy tumour as large as a child's head, of more than four years' duration. There had been rapid increase for two months; pain had been present only three weeks. There was no gland enlargement. The patient was in robust health. The great bulk of the mass consisted of solid, white fibrous tissue studded with microscopic cysts. Amid this, however, was a small region not larger than a hazel nut, of greyish colour and soft consistence, consisting of embryonic spindle cells in bands (spindle-sarcoma). The disease recurred under the scar

in the following September, this time showing sarcoma tissue only, and again in April, 1894, when the whole parietes in the vicinity were found extensively infiltrated. Text-books confounded the connective-tissue overgrowths appearing during the development of the mamma with those attendant on its devolution or permanent decay. The "fibroma of adolescence" appeared in young girls from fifteen to twenty-five, was hardly ever accompanied by cyst formation, was often multiple, attacking both breasts, was never associated with cancer, except casually, and commonly yielded to suitable local treatment or spontaneously disappeared. On the other hand, the "cystic fibroma" of women past thirty-four was always associated with cysts, formed a single, slowly growing, bulky mass, and eventually passed always into a malignant lesion, sarcoma or carcinoma. The redundant white fibrous tissue failed as age advanced to undergo organisation, and merged into spindle-celled sarcoma; or else the included islets of acinous epithelium developed scirrhous carcinoma of the ordinary type. The point had a significant bearing upon the general question of cancer etiology.

Mr. SHATTOCK gave two short communications, one on Diphtheria and Pseudo-Diphtheria Bacilli from two sisters simultaneously affected, and the other upon Cultural Variations of *Streptococcus Pyogenes*.

The following card specimens were exhibited:—

Dr. H. M. FLETCHER: Secondary Sarcoma of Lung.

Mr. S. PAGET: Unusual Form of Stricture of Oesophagus.

Mr. W. H. BATTLE: (1) Melanotic Sarcoma of Clitoris; (2) Unusual Effects of Bullet Wound of Vault of Skull; and (3) Diffuse Tuberculous Infiltration of Tibia.

Dr. H. MACKENZIE: (1) Liver with Abnormal Lobes and Multiple Gummata; and (2) Emphysema of Intestine.

Mr. RUSSELL WELLS: Replaced Trephine Circle of Bone.

Dr. CYRIL OGLE: Ulcerative Colitis.

The business of the annual meeting was then proceeded with. The report of the Council showed that the affairs of the society were in a satisfactory state. The introduction of experimental pathological work had stimulated the attendances at the meetings and had brought forth much valuable material. The usual votes of thanks to the retiring officers were carried.

The following is a list of officers for the ensuing year:—

President: Henry Trentham Butlin, D.C.L., F.R.C.S. Vice-Presidents: Thomas Barlow, M.D., William Selby Church, M.D., Norman Moore, M.D., Seymour Sharkey, M.D., Alban H. G. Doran, Frederick S. Eve, Cuthbert H. Golding-Bird, and Frederick Treves. Treasurer: Sidney Coupland, M.D. Honorary Secretaries: G. Newton Pitt, M.D., and J. H. Targett, M.S. Council: Wilmot Parker Herringham, M.B., A. A. Kanthack, M.B., Hector Mackenzie, M.D., Sidney Martin, M.D., William Pasteur, M.D., H. D. Rolleston, M.D., Charles Scott Sherrington, M.B., F. Charlewood Turner, M.D., A. F. Voelcker, M.D., Dawson Williams, M.D., Gilbert Barling, M.B., Jones Berry, M.B., Stanley Boyd, Anthony Bowly, E. Hurry Fenwick, C. B. Lockwood, Stephen Paget, Bilton Pollard, M.B., Samuel G. Shattock, and Charles Stonham.

HUNTERIAN SOCIETY.

The Necessity for a Central Organisation in the Medical Profession.

A MEETING of this society was held on April 24th at the London Institution, Mr. CHARTERS J. SYMONDS, President, being in the chair.

Mr. F. R. HUMPHREYS read a paper on the Necessity for a Central Organisation in the Medical Profession, illustrating his arguments by facts derived from the experience of himself and others, so as to show the necessity for speedily meeting the evils described. The lay medical aid associations were first attacked, and reference was made to the resolution of the General Medical Council, which had appointed a committee to consider the question and had come to the conclusion that these associations overworked their officers and underpaid them. It was unfortunately the case that some men would not allow any mere ethical questions to prevent their acquiring practices at the expense of their neighbours. Lay companies must be fought with capital if they were to be beaten. Provident dispensaries appeared to have been established early in the century, and not only now were the rates for members too

low, being at the highest 7½d. for a visit or consultation, but a great part of the money was expended on unnecessary premises and officers. Mr. Humphreys gave a few instances of payments at various provident dispensaries, including Tunbridge Wells, Reading, Leamington, and Salisbury, showing the latter to be the only one which attempted to pay the medical men properly. In the case of sick clubs, which were provident societies without wage limit, the club officer received usually from 3s. 6d. to 5s. per head per annum, but in the country these clubs rarely paid their medical men more than 4s. per head per annum, a sum which could not be remunerative, but which would be accepted in order to avoid competition. It was simply impossible for a dispensary practitioner to comply with the requirements of medical practice while charging such fees. He must be dishonest in some direction in order to make enough to live upon; and inferior and insufficient drugs, unqualified assistants, card advertising, &c. were a few of the common evils attached to "cheap dispensaries." The only way to avert these evils lay in a properly worked provident system, under which charges, fair alike to medical men and patients, were made. The present condition of things would not be long tolerated if thoroughly exposed through the medium of a representative committee under the Royal Colleges taking evidence like a House of Commons select committee, as already proposed by Mr. Bryant. It was estimated that in London one in every two persons received charitable medical relief at the out-patient departments of hospitals, and from figures given by Dr. Rentoul it would appear that 50 per cent. were unsuitable cases. Mr. Humphreys then read part of a letter from a medical man who had acted as locum tenens last July at a public dispensary, where he had to see 210 patients in three hours, a hundred more applicants being dismissed with "repeat" medicines. Many of the cases were utterly unsuitable, and some came from Gravesend and other equally distant places to be treated with medicine for a week for sixpence. Another evil connected with hospitals was the pay ward. If a medical man could send his patients to the pay wards of a hospital and attend them there it would not matter, but when once they were within the hospital walls they were practically lost to the outsider. A further danger threatened in the shape of nursing homes where patients were either attended by no medical man at all or by one specially appointed to the institution. No medical man should patronise these nursing homes unless the patients were under medical advice. Another important question was that of the relations between consultants and general practitioners. The junior consultants had very inadequate remuneration, but if the leading physicians would take fees corresponding to their position the difficulties would be less. Much might be done if those practitioners who were willing to act as pure consultants were to state this fact in some binding way. The term "infamous conduct" had been much objected to as meaning one thing to the profession and another to the outside public. Mr. Humphreys had written to Sir Richard Quain asking him if the General Medical Council would be likely to approve of an organisation to promote discipline in the profession. Sir Richard Quain replied that he was confident that the Council would keep within its statutory authority, which does not enable it to interfere in the internal discipline of the profession; and in another letter he said that it would be quite impossible for the Council to strain its powers in that direction. Under these circumstances what controlling influence could be devised? Mr. Humphreys himself proposed a union of medical associations, whose delegates should form local boards, and these in turn appoint directors.

The CHAIRMAN then asked for opinions on the best way of meeting the evils complained of, whether by means of purely moral and ethical influences or by the establishment of an ethical association to which every man would belong, non-membership marking him as not respectable. It had been suggested that the best remedy for the special evils attending provident societies was that all the medical men in a particular district should combine together to form a provident society of their own, the fees being used for the payment of the members.

Mr. BRYANT said that the diseases of the body corporate needed attending to just as much as the diseases of the body corporal. Most of the faults that existed in the profession arose through competition; but what power had the General Medical Council to influence those who undersell? It was not only in the lower grades of the profession

that this under-bidding went on, but in the higher grades as well. Five years ago the Government was asked by the Royal College of Surgeons of England for further powers, but it would not grant them. It had been again approached on the subject and a series of by-laws put before the Home Secretary. Since the question was put before the Home Secretary an association had arisen speaking in the name of the Members of the Royal College of Surgeons of England and asking the Home Secretary not to grant the desired powers. The only mode of punishment was by removing the names from the list of Members of the College, but that seemed to be too severe. It was easy to take a diploma away, but not so easy to restore it.

Dr. GLOVER said that he was disposed to agree with Mr. Bryant that the powers of the General Medical Council were too limited to permit of its doing anything. He did not think that any attempt to interfere with the practice of medical men would have the support of the Council. It had been already tried and the Council declined to pass any judgment upon the conduct of the men. The medical corporations might do more than they did, the power of the General Medical Council being reserved for extreme cases. The medical corporations would condemn what seemed to be a contempt for their authority. They would take the name of a medical man off their list and they would deprive him of his diploma, but the man from whom the diploma was withdrawn would use his title, and continue to do so, without the slightest sign from the corporation which had withdrawn the diploma. Could anything be more obvious than that it was the duty of the body whose rules had been defied to bring that man to court? In every locality there should be an association of medical men to bring pressure to bear upon those who did these things.

Dr. ALDERSON said that the out-patient departments of hospitals had done a grievous wrong to the general practitioner. He wished to support the proposition made by Colonel Montefiore as to the desirability of a Central Board. Such a board would prevent the starting of unnecessary special hospitals merely for the benefit of one medical man. As to the sick club system, the General Medical Council could not do much, but some improvement might be expected to result from higher education. He agreed with Dr. Glover that the profession must not be made into a trade, and approved of the suggestion that medical men should not be allowed to dispense their own medicines.

Mr. COTMAN said he was under the impression that the General Medical Council was competent to declare what was infamous in a professional respect. Without combination nothing could be done, and medical men should combine in the various districts in which they live.

Dr. CAMPBELL POPE thought that the General Medical Council would greatly help if they could define some degree of misconduct less strong than that which was termed "infamous." Being struck off the Register was a very serious thing, and if something less severe could be arranged it would have great effect. The Council should also notify to the registrars the names of those who had been struck off the Register. The practices which came before the society were canvassing patients for clubs and sending out advertisements, and such cases should be reported to the corporations from which the offenders received their diplomas. Many patients with good incomes were going daily to various hospitals, and the special hospitals were patronised by a better class than the general ones, as had, in fact, been pointed out by the managers of special hospitals themselves. There was a certain flavour of charity connected with the general hospitals, and people did not like to say they had been to Guy's or St. Bartholomew's or University College Hospital, but they did not object to say that they had obtained advice at the Hospital for Paralysis or for Diseases of the Eye or the Skin. Moreover, there was only one University which could remove a member for misconduct, and many men who had been deprived of their diploma still flourished their University degree in the face of the General Medical Council. As Mr. Bryant had remarked, the reform must come from the conscience of the man.

Mr. SMALLPEICE said that the corporations and colleges might influence erring members by censuring them without removing them. What was wanted was an ethical association in some form which should be regarded as authoritative.

Dr. CAGNEY said that he did not believe that any medical council would have the power to deal with this question. Medical men did not require looking after more than any other

body of men, and conscientious medical students would do all that was required to raise the condition of the profession.

Mr. HUMPHREYS, in reply, said that those men who charged unremunerative fees were degrading the whole profession, and some protection against them must be found. Medical etiquette had no weight at all with such men.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

The Relations between the Conditions of the Soil and the Prevalence of Epidemic and Endemic Diseases.

THE last meeting of the session of this society was held on May 17th, Mr. SHIRLEY F. MURPHY, President, being in the chair.

Brigade-Surgeon-Lieutenant-Colonel LANE NOTTER, M.D., Professor of Military Hygiene at Netley, read a paper on the Relations between the Conditions of the Soil and the Prevalence of Epidemic and Endemic Diseases. Some such influence had, he said, been recognised from the time of Hippocrates, but the scientific study of the geographical distribution and seasonal prevalence of diseases was of quite recent growth. Pettenkofer, von Fodor, Hirsch, Fleck, Schlössing and Müntz, Lewis and Cunningham, and others had taken up different aspects of the question; but while many of the phenomena of disease were clearly referable to telluric conditions, the fact that these conditions were for the most part processes in which numerous factors were involved, some coöperating and others mutually antagonistic, rendered their investigation difficult even for limited areas. We might consider the complex result and the effects of the several factors, but again our knowledge even of these was imperfect—e.g., as regards the organic acids and other bodies which, together with salts, water, air, and carbonic dioxide, went to make up the food of plants. Among the diseases which were evidently influenced by soil conditions were cholera, diphtheria, enteric fever, diarrhoea, malarial fevers, phthisis, rheumatism, yellow fever, dysentery, and a few others. *Cholera*.—Its importation was a necessary condition, save in regions where it was constantly present, but there were localities, as Pettenkofer had pointed out, where it always assumed a severe type, and others the sanitary conditions of which were no better where it never established itself. The bacillus was easily identified, though it was not certain whether the coöperation of others was not required for the production of the full effects. In this country drinking water was, at any rate for many years past, the chief or sole vehicle of infection, but in Germany the ground water was held to exert a powerful influence, Pettenkofer maintaining that cholera never prevailed where the level of the ground water was fixed and constant, or in absolutely impervious soils, where, in fact, there was none, since by the rise and fall of the ground water wells became infected, and, as Pfeiffer argued, the movements of the ground water were the index to the moisture, aeration, and temperature of the surface soil, the home of all bacteria. Aridity, or prolonged drought, and very heavy rainfall or submergence were alike unfavourable to the spread of cholera, severe epidemics occurring in India only during light, warm rains in arid regions, such as the Panjab, and in the comparatively dry intervals following the rains in humid Bengal, though other causes, as human intercourse and habits, were concerned in its diffusion. Its favourite haunts were sandy soils alongside large rivers or in the proximity of tanks, but the bacillus or vibrio, though often found in tanks or filters, had not yet been detected in the soil. Feeble as they were, they had been observed to multiply in moist, warm soil for forty days, and in a mixture of soil and sterilised faeces for twenty-eight, though in the presence of crude faeces they perished within a week. *Diphtheria*, though propagated mainly by personal intercourse, recurred year after year in the same places, as if connected with the soil, and it seemed to prefer clays, but probably the nature of the soil mattered little so long as it was cold and damp. In moist earth, at a temperature not over 14°C. and in the dark, cultures could be maintained for four months; but warmth, dryness and light were fatal to them in a short time. Adams had sought to show a relation between outbreaks of diphtheria and the movements of the ground water, but we knew too little of these in this country, and other factors were so powerful that

there was no evidence in support of this view. The influence of temperature and moisture fully explained its absence from the plains of India and its prevalence in the hill stations with their more European climate. *Enteric fever* was universally distributed, but outbreaks were always strictly local. Nowhere did elevation have any real influence, but it was more frequent on recent formations, these being the more permeable. Ranke at Munich and Cameron in Dublin observed its prevalence on pervious, sewage-sodden soils, the agency of drinking water being excluded, and the movements of the ground water and ground air, especially a rapid fall as Pettenkofer maintained, the only possible exciting cause. The presence of the bacillus in the soil had not been demonstrated, but experiments had shown that it lived longer in moist soil than in dry, and in garden earth than in pure sand, while it died out very soon in peat. The experimental evidence of dried enteric excreta being conveyed as dust had a direct bearing on a possible danger from the use of earth closets, especially in India. *Diarrhæa*, as occurring in summer and autumn, was evidently dependent on the presence of putrefying organic matter, not necessarily faecal, and on permeability of the soil, being rare on slates and granite, and not specially prevalent on clays. Ballard first called attention to the influence of high temperature of the soil, not of the air alone, the mortality rising when the temperature of the earth at a depth of four feet reached 66° F., and declining a week after it had sunk to 60° F. No specific bacillus had been shown, but the putrescence of foods, especially milk, was a most important factor in its causation. *Malarial fevers*, depending on the presence of organic matter under certain conditions in the soil, were greatly influenced by the movements of the ground water and ground air, which was aspirated by the reduced pressure of an atmosphere warm and laden with moisture, as in some tropical regions and in all warm and temperate climates in summer and autumn nights, or escaped when the soil was turned up. The poison was air-borne and not carried by dust, desiccation and submergence alike arresting its diffusion, though it would be taken in by drinking the water of malarial districts. The microbe was most probably protozoic, an amoeba, the plasmodium of Laveran, the "spores" of which stored in the spleen sent out successive broods of the organism. It had, however, not been observed or cultivated out of the body. *Phthisis*.—The observations of Middleton, Buchanan, and Bowditch on the relation between the prevalence of phthisis and dampness of soil and the decline in the mortality that followed the better drainage of certain towns were well known, but had been severely criticised. Kelly had shown that phthisis preferred cold, damp, bleak localities whatever the soil, and it was frequent enough among persons in ill-ventilated, overcrowded rooms. In fact, whatever conditions excited catarrhs of the respiratory organs predisposed to phthisis, catarrhs constituting the non-tuberculous forms and inducing susceptibility to tuberculous infection. Improved social conditions of the town populations should be considered. *Rheumatism*.—There was really little or nothing in common to the two diseases called acute and chronic rheumatism, names which were relics of obsolete doctrines. Chronic rheumatism was set up by exposure to cold and damp. Acute rheumatism seemed to prefer a warm, dry soil, and to assume an epidemic character in years of small rainfall and low ground water. The tendency of recent thought was to look on it as a soil-bred bacterial disease in some respects akin to erysipelas. *Yellow fever* was confined to the banks of rivers and seaports in the tropical zone of the Atlantic, where the polluted mud was alternately flooded and dried, and the foreshores had not been covered by shingle or docks and quays. Creighton's theory of its evolution from the filthy bilge-water of the slave ships, saturated with the excreta of dysentery and typhus-stricken negroes, had much in its favour. The microbe, undoubtedly propagated in the mud, had not been certainly isolated.

Dr. SALTET (medical officer of health of Amsterdam) said that agues, so prevalent in Holland forty years ago, had become rare since the substitution of steam pumping engines for windmills rendered it possible to keep the ground water at a constant level.

Dr. NEWSHOLME (medical officer of health of Brighton) regretted that owing to the neglect of Pettenkofer's teaching there were in this country no regularly recorded observations of the movements of the ground water, except in Brighton

and Croydon, such as were taken daily at sixteen stations around Berlin. Under present conditions it would seem that an impervious soil was likely to be more healthy than a pervious one. In comparing the frequency of epidemics on different soils the numbers of the population living on each should be taken into account. It was instructive to contrast phthisis and diphtheria, in which the same factors of soil &c. and personal intercourse were concerned, but inversely; so that while it was not easy to prove infection in phthisis, the influence of soil was totally obscured in diphtheria; and while the former had decreased under improved social conditions the latter had, at certain ages at any rate—viz., those of school life—increased.

BRITISH GYNÆCOLOGICAL SOCIETY.

Pregnancy complicated by Suppuration within the Pelvis—Exhibition of Specimens.—Intra-uterine Stems.

A MEETING of this society was held on May 9th, Dr. CLEMENT GODSON, the President, being in the chair.

Dr. H. MICHIE (Nottingham) read a paper on *Pregnancy complicated by Suppuration within the Pelvis*. He said that his attention had been called to this subject by a paper read before the society in February, 1891, by Dr. Grigg, on the influence of Pre-existing Inflammatory Disease on the Puerperium. He thought that the vague expression "puerperal fever" should be given up, just as the term "surgical fever" had been discarded; he believed that the two diseases were due to similar, if not identical, causes. He related six illustrative cases, which fell naturally into three groups—viz., (1) perforation of the vermiform appendix, giving rise to abscess within the pelvis; (2) suppurative peritonitis due probably to pre-existing disease of the uterine appendages and operated upon after delivery; and (3) suppuration of the appendages operated upon during pregnancy. Group 1 was represented by one case, a patient in the fourth month of pregnancy whose symptoms and physical signs pointed to disease of the appendix. Abdominal section was performed, when the ruptured appendix and an escaped concretion were removed. Recovery was uneventful and natural delivery occurred at term. Had the complication arisen at or near the time of delivery it might have been overlooked, and the practitioner might have been accused of neglecting the use of proper antiseptic precautions. Group 2 contained two cases. The first of these patients was seized five days before labour with acute abdominal pain, the symptoms subsiding with rest, but being aggravated by the delivery. She rallied slowly till the sixth day after labour and then became rapidly worse. She was operated upon without delay, and about three pints of thin offensive fluid were evacuated from the abdominal cavity. The Fallopian tubes, which contained pus, and the ovaries, which were gangrenous-looking and studded with small abscesses, were removed and drainage used. Recovery was slow but uninterrupted. The second case of this group was very similar. The patient miscarried in the sixth month of her first pregnancy after having had a profuse yellow vaginal discharge for six weeks. The appendages in this case did not seem so much diseased and were not removed. The patient's recovery was satisfactory and she was now seven months advanced in her second pregnancy. These two cases were, in fact, instances of puerperal peritonitis commencing before delivery. In the second case there was a definite history of gonorrhœa. Group 3 consisted of three cases. The first patient was seized with severe pain during the fourth month of pregnancy. The uterus was retroverted. Abdominal section was performed and both Fallopian tubes were removed. The left one contained pus; the right one was thickened and inflamed, but not otherwise diseased. The patient recovered rapidly; pregnancy proceeded to term and the labour was natural. The second case was a multipara aged forty years, from four to five months pregnant and suffering from gonorrhœa and peritonitis. Immediate operation was advised, but the patient delayed it for four days, at the end of which her pulse had risen from 98 to 128 and all the symptoms had become worse. The pelvis contained about half a pint of sero-purulent fluid and there was double pyosalpinx. The appendages on both sides were removed and a rubber drainage-tube was inserted. She went on well for two days and then miscarried; soon afterwards all the symptoms of

acute septic peritonitis set in and death ensued on the sixth day. The last case was a married woman aged twenty-two years, the mother of two children. She ceased to menstruate in May, 1892; in August she had at irregular intervals labour pains, with discharge of blood from the vagina. When seen in October the abdomen contained two tumours. One, on the right side, was fixed, smooth in outline, reaching to the umbilicus, and almost filling the pelvis; in the pelvic part fluctuation was felt. The other tumour, on the left side, was movable, uniform and smooth, and reached nearly to the costal cartilages. The os uteri was close behind the pubes and was dilated to the size of a florin; a foetal head was presenting, the membranes being unruptured. The next day labour pains came on strongly, blood-clots were passed, the patient suffered from rigors and vomiting, her pulse rose to 136, and her temperature to 103.6° F. On the following day, her condition being critical, the abdomen was opened and a cyst of the right ovary universally adherent and containing fetid pus was removed. The operation occupied fifteen minutes and labour was completed four hours afterwards. In the evening there was much distension and a glass drainage-tube was introduced. There was gradual improvement till the sixth day, when distension having returned the drainage-tube was reintroduced and a quantity of sero-purulent fluid was withdrawn. Three days later the tube was finally removed and recovery proceeded without interruption. Thirty-three days after the operation the patient was discharged recovered. In March, 1894, she returned and was found to have a small ovarian cyst on the left side. This was removed and it was observed that all the previous adhesions had disappeared. She went home fourteen days after the operation. Although in the great majority of instances puerperal peritonitis arises from septic material introduced during or soon after labour, these cases show that occasionally it might originate in pre-existing inflammatory conditions, and might be altogether independent of immediate infection from without. — The PRESIDENT regarded Dr. Michie's paper as one of special value. He had seen a case at St. Bartholomew's Hospital very like the first one related. The patient suffered from fever, pain, and vomiting, and peritonitis was diagnosed. In twenty-four hours labour came on and death ensued. At the necropsy a ruptured vermiform appendix was found. In another instance a patient died during pregnancy, probably from a ruptured pyosalpinx. Operation was advised, but was not allowed. Dr. Michie's paper would help to exonerate men who were in some cases unfairly accused of having conveyed infection to their patients.—Dr. LEITH NAPIER, Dr. ROUGH, and Dr. KEMPSTER joined in the discussion, and Dr. MICHIE briefly replied.

Mr. JESSETT showed two specimens: 1. A Large Fibroid of the Uterus, the whole organ having been removed by Abdominal Hysterectomy. The patient's mother had been operated on by Mr. Jessett eight years previously for uterine fibroid. Trendelenburg's position was used. A long, specially made speculum was passed high into the vagina. Peritoneal flaps were reflected from the tumour and the speculum was cut down upon. The uterine arteries were tied, the broad ligaments cut through, and the whole organ lifted out. Ligatures were passed through the peritoneal flaps, without tying, and their ends, left long, were drawn down through the vagina. The patient was making an uneventful convalescence. This was his fifth case treated by this method. 2. A Case of Hematosalpinx. Blood was found in both tubes; one of them ruptured during operation, allowing old dark blood-clots to pass into the pelvis. The patient made a good recovery.

Dr. HEYWOOD SMITH showed two specimens: 1. Migrating Ovarian Dermoid. The uterus in this case was retroflexed in such a way that when replaced in its normal position it fell back with a jerk. The tumour was to the right of the uterus, but was found to belong to the left side. The left Fallopian tube passed in front of the uterus, so as to hold it in a backward position. The ovary and tube of the right side were deep in the pelvis and atrophied. The patient made a good recovery. 2. Sarcoma of the Uterus removed by Vaginal Hysterectomy. Before operation a fragment of the growth was examined by a pathologist, who reported it to be sarcomatous. Owing to the difficulty of applying ligatures in this case the broad ligaments were secured with Braithwaite's clamp forceps. The patient was progressing satisfactorily.

Dr. MACNAUGHTON JONES showed for Dr. DUKE some

Intra-uterine Stems, as well as one of his own. He never himself used them except after division of the cervix for stenosis and dysmenorrhoea. Much of the harm caused by stems was due to their being too long.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Multiple Diabetic Neuritis.—Skin Grafting from the Lower Animals.—Exhibition of Cases, Specimens, and Drawings.

THE tenth meeting of this society was held on May 15th, Dr. CLOUSTON, President, being in the chair.

Professor T. R. FRASER read a paper on a case of Multiple Diabetic Neuritis. The patient, a man, thirty-two years of age, sought admission to the Glasgow Royal Infirmary on account of general weakness, and was found to be suffering from diabetes. He had previously undergone severe anxiety through the prolonged illness of his wife. He improved under treatment and was able to return to work, but after some time he relapsed and was taken into the Edinburgh Royal Infirmary. On admission, being on ordinary diet, the urine contained on an average 7178 grains of glucose in twenty-four hours, but with restricted diet the amount was 3622 grains in the same period. While he was taking pancreatin the average excretion of glucose fell to 1716 grains in twenty-four hours. From the time of admission there was pain in the calves and ankles, which had persisted for three months. He felt neither numbness nor abnormal sensations. The sensations to heat and cold in the limbs were normal. There was marked pain on pressure in the legs, pectoral muscles, and biceps. The knee-jerks were absent. The gait was normal. Vision was diminished; a central scotoma for red was present in both eyes. Notwithstanding the diminished excretion of sugar the patient's general condition deteriorated, and the chloroform-like odour, which had been present from the time of admission, became more marked. Dyspnoea, orthopnoea, and coma ensued, and were followed by death. Post mortem phthisis was discovered, but no other gross lesion. The disease was probably a toxic neuritis caused by a poison derived from the sugar.—Dr. ALEXANDER BRUCE gave an account of the post-mortem examination. The optic nerves, specimens of which were stained by the Weigert-Pal and Marchi methods, were much degenerated in the centre. The right posterior tibial nerve was undergoing parenchymatous neuritis, and the corresponding nerve on the left side showed a like degeneration, but in a less degree. The gastrocnemii muscles, stained by Marchi's method, showed between the muscle columns little rows of black dots in the binding substance resulting from fatty degeneration. The muscle striation seemed practically normal.—Dr. JAMES said that he had two recent cases of neuritis in his wards, one in a patient suffering from diabetes and the other in a case of advanced phthisis. The concurrence of neuritis with tuberculosis was incompatible with any toxic theory with regard to sugar.—Dr. G. A. GIBSON said that multiple neuritis occurring in diabetes seemed to be independent of the amount of sugar present. There is an analogy between alcoholic poisoning and the condition now under discussion, and there must be some form of toxæmia that causes the neuritis. He advanced the view that rigid diet was sometimes inadvisable, tending to increase the acidity of the blood, whereby fermentative processes were set up in which acetone was the last development.—The PRESIDENT said that these histological changes might be compared with certain cortical changes found in diabetic insanity. In one such case Dr. Clark had found decided changes in the nerve cells of the cortex. Diabetic coma and congestive effects, no doubt arising in the vaso-motor centres of the cortex, might be accounted for on the toxic theory. The boils which sometimes occur might be connected with toxic changes in the nerves of the skin.—Professor FRASER then replied.

Mr. ALEXANDER MILES read notes on Skin Grafting from the Lower Animals. Of the different methods of skin grafting Thiersch's gave the best results, but it had the disadvantage of necessitating the use of chloroform. There was also the difficulty of obtaining skin. The lower animals, however, were always available. In his cases dogs, rabbits, cats, and frogs had been employed, and dogs had been found the most satisfactory. Young animals were used, their skin

being preferable. The ulcer was prepared as for any grafting. Scraping was not necessary; in fact, it was to be deprecated. The animal having been killed, the abdomen and flanks were shaved and purified, and the skin was dissected up and floated out in warm boracic lotion. The size of the graft varied up to six inches by one inch. The graft was placed on the ulcer and pressed down; the ulcer was covered as completely as possible and a dressing applied. Success depended on the subsequent dressing. The first dressing should not be done until at least forty-eight hours had elapsed, and should be delayed longer if possible; the greatest care must be taken to avoid disturbing the grafts. Complications might arise, such as sloughing of the graft (possibly caused by too early dressing), hæmorrhage under the graft, &c. The situation of the ulcer might require modification of the treatment. On the thorax the bandage should be very loose so that the grafts might move with the chest wall. Ten cases were quoted, in four of which the results had been eminently satisfactory. In two of them amputation—which had been recommended and for which the patients were anxious—was avoided. Four cases were partially successful and two were failures. After grafting, the scars were stronger than ordinary cicatrices, and no hair, pigment, or sweat glands were present in them.—Mr. JOSEPH BELL said that he had a good deal of experience some years ago with Reverdin's method of skin grafting. He had almost exclusively used tame white rats, the young of which supplied an excellent plastic skin. It was of importance not to take the subcutaneous fat in removing the skin. The grafts were put on granulation tissue. He never scraped if he could help it, and agreed with the recommendation that there should be no dressing before forty-eight hours. In dressing, the difficulty was to make the grafts adhere in mobile parts such as the thorax. He used small pieces of protective a quarter of an inch square, applied in large numbers one above another like the scales of an armadillo, the idea being that in movement the pads of protective moved on each other, and so did not disturb the grafts. Long ago David Hamilton suggested sponge grafting. The results were most extraordinary, the sponge seeming to act as a matrix or support for the granulations. He mentioned a case where a large mass of sponge placed in the axilla became embedded in granulations.—Mr. A. G. MILLER said that whatever resulted from skin grafting was not true skin, but cicatrix. Some grafts did more good than others, skin being the best. Sponge grafting was mainly useful for the protection of granulations; it also helped cicatrization, but not so well as skin grafting.—Mr. CATHCART thought the advantage of Mr. Miles's method over Thiersch's was, as had been said, the absence of the necessity for giving chloroform. The results also were as good. Young pigs might be useful as a source of grafts, but they were expensive.—Mr. WALLACE said it was quite intelligible that no hair or sweat glands should be present, for in making the Thiersch graft they did not cut deep enough to take glands but only the tips of the papillæ, just enough to draw blood. Personally he leaned to Thiersch's method rather than to grafting from the lower animals. They could, as a rule, get the patient to consent to the administration of an anæsthetic, and could take large portions of skin from the front of the thigh.—Mr. MILES then replied.

The PRESIDENT showed a patient who had recovered from Insanity under treatment with Thyroid Extract, administered in large doses till what might be termed a septic thyroid fever was set up. After from three to six days the extract was discontinued and the patient was nursed in bed. The effect on nutrition in successful cases was well marked. The thyroid extract seemed to stimulate the trophic centres and the patient gained weight rapidly.

Mr. CATHCART showed two male patients with Venereal Warts. The cases exemplified the fact that venereal warts might be acquired without any irritation from gonorrhœal discharge, neither of the patients having had gonorrhœa.

Dr. ALEXANDER BRUCE showed specimens of the Embryo *Filaria Medinensis*. The embryos were exhibited free and also in the host, the minute freshwater cyclops.

Dr. G. A. GIBSON showed: (1) Drawings of a Brain from a case of Porencephaly, and from a case of Thrombosis of the Lateral Sinuses and Cerebral Veins in which there was red softening of the internal capsule; and (2) Photographs from a patient suffering from Double Facial Paralysis, and from a patient suffering from Alternate Paralysis from a Lesion of the Crus Cerebri.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Excision of the Rectum.

A MEETING of this Section was held on April 26th, the President, Mr. W. THORNLEY STOKER, being in the chair.

Mr. HEUSTON read a paper on Excision of the Rectum in Malignant Disease implicating the Middle Third of the Bowel, advocating a modification of the old perineal operation in such cases. He gave the history of two cases in which he had operated, the first being that of a man aged fifty-nine years who had an ulcerated growth implicating the anterior aspect of the bowel to the extent of three inches from immediately above the internal sphincter, and intimately attached to the prostate gland; this, on microscopic examination, was shown to be cylindrical epithelioma. The patient was sent home three weeks after operation with full and natural control over his bowel. Three and a half years have elapsed since the operation, and there has been no evidence of recurrence of the disease. The second case was that of a woman aged fifty-one years who had an ulcerated growth situated on the posterior wall of the bowel, the lower border of which was between two and three inches from the anus, from which it extended upwards for about two and a half inches, being attached to the anterior aspect of the sacrum. This patient was allowed to go home thirty-one days after operation, having perfect control over her bowel. Nearly three years have elapsed since the operation, and no further evidence of disease has appeared. The operation performed was as follows. An incision is made from the rectum to the coccyx, severing the attachment of the external sphincter and levator ani muscles from the ano-coccygeal ligament; the rectum is then separated from the tissues, and clip forceps are applied at the commencement of the ampulla, below which the bowel is divided in its entire circumference and then drawn down and the diseased portion removed. The upper portion of the bowel is fixed in its position by a row of sutures about an inch above its cut extremity to the pelvic fascia and levator ani muscle; these sutures should not penetrate the mucous coat of the bowel; the object of the first row of sutures is to prevent tension on a second row, uniting the cut extremity of the bowel to the portion of the intestine with the sphincters and levator ani originally left below the section of the bowel. Mr. Heuston claimed for the operation that it is a less serious one than any of those requiring removal or displacement of the coccyx and part of the sacrum, that the peritoneal cavity is not usually opened, the normal function of the bowel is preserved, subsequent stricture is not so liable as after the usual perineal operation, convalescence is rapid, the mortality low, and the disease is not more liable to recur than after the more extensive operations.

The PRESIDENT said that within the last few years the treatment of cancer of the rectum had attained a very satisfactory development. He entirely disagreed with Mr. Heuston regarding the removal of cancer of the rectum by the perineal as compared with the trans-sacral operation. He had at present two patients in the Richmond Hospital, both of whom he could not have ventured to touch by the perineal method. He did not dread the opening of the peritoneum. Cancer of the middle third of the rectum could not be removed by the perineal operation without opening the peritoneum—if, as Mr. Heuston stated, the peritoneum often came down to within one inch and a half to two inches of the sphincter. It was better to open the peritoneum by an operation which gives a perfect view, such as the trans-sacral method does. Personally he preferred the lateral semiprone position to having the patient placed on his back.

Mr. BALL said Mr. Heuston's paper had raised what the President had described as a test between the perineal and trans-sacral excision of the rectum. He did not think there was any doubt that both of these operations had their right place. The perineal excision of cancer must be kept for a very small minority of cases in which the disease is very close to the anus. The so-called trans-sacral operation need not necessarily be a trans-sacral one when the cancer was low down. Quite sufficient room could be obtained by dividing the coccyx from the sacrum without cutting the sacrum at all. The additional room gained by removing the sacrum is

very great indeed. Only a day ago he had seen a woman in whom he had divided the sacrum trans-sacally two years previously. At the time he was quite unable to estimate the extent of the disease. In this case he had to remove nearly the whole of the rectum and, perhaps, part of the sigmoid flexure—in all, six inches. He had then to divide the mesentery of the rectum or sigmoid flexure to some extent, so as to be able to bring down the intestine sufficiently to stitch it to the intestine and anus left in the floor of the pelvis. It was an ideal result, there being complete and absolute union between the upper and lower parts of the intestine. The floor was not disturbed. The operation had been conducted above the levatores ani. He did not quite follow Mr. Heuston's description of the operation he performed. Did the incision from the anus to the coccyx involve the anus or start outside it? If it did not involve the anus it was the operation selected by everybody in suitable cases. The coccyx could be excised, or the sacrum, up to the third sacral foramen. Above this foramen the bladder would be paralysed.

Mr. CROLY said that Mr. Heuston stated some of his patients suffered from intense pain. His experience of cancer of the rectum was that it was constantly overlooked till it had progressed too far. If he could not get his finger above the diseased part he either left the case alone or performed a colotomy. He thought whether the lymphatic glands were implicated or not was a very important point. He would like to know the condition of the patient in a few months.

The PRESIDENT said that in one of his cases he found considerable implication of the lymphatic glands, and that he readily removed them as high as the brim of the true pelvis. The trans-sacral operation gave great opportunity for examining the pelvis.

Mr. FRANKS said that in a case of cancer of the rectum high up he would prefer a trans-sacral operation. Of all situations in the body, with the exception of the lower lip, cancer of the rectum offers the best hopes of non-recurrence. The disease usually lasts a considerable time before it invades the glands. Mr. Heuston's case was one in point. In a woman whom he had operated on the disease involved the anus and extended up three inches. He removed the whole anus, and brought down the bowel and sutured it to the skin. He saw her nine years after the operation and there was no return of the disease. She had no trouble although she had had no sphincters during this time. In another case, in which the disease extended as high up as he could feel, he had considerable difficulty in removing the rectum and afterwards discovered that the disease had been treated elsewhere by caustics and the cautery. This patient lived for three years, after which he lost sight of the case. If the growth were irremovable the French method of proctotomy was better, in his opinion, than colotomy.

Mr. WHEELER said that with regard to the recurrence of cancer of the rectum, his experience was not so favourable as that of Mr. Franks. He did not agree with him that patients objected to colotomy; they might have disliked the lumbar form.

Sir W. STOKES said that up till now he had followed the teaching of Professor Syme, who laid down that all cases of cancer of the rectum that were beyond the reach of the finger were unfit for operation. Now, however, he had changed his opinion. He had only operated by the old perineal method on cases in which the disease was near the anus. His results were mostly very satisfactory.

Mr. THOMSON believed that prognosis of cancer of the rectum was more favourable than in most other parts of the body. When the cancer was close to the anus he agreed with Mr. Ball that the perineal operation was the proper one to adopt. When the disease was higher up he had no doubt that the trans-sacral method was the best. It gave most room, and enabled the parts around the seat of the disease to be thoroughly examined. There was very little hæmorrhage, and it was easily controlled.

Mr. HEUSTON, replying, said he did not recommend the perineal operation in a certain class of cases. He did not agree with the President that the peritoneum must be opened if the disease occurs in the middle portion of the rectum. On the anterior aspect the rectum could be removed as high as the prostate, on the lateral aspect $4\frac{1}{2}$ in. of the bowel could be removed, and 5 in. on an average behind, without opening the peritoneum. If the peritoneum was opened it could be effectively closed by the deep row of sutures. He agreed

that the trans-sacral operation is the best where the disease is high up in the bowel or where there is much implication of the glands of the pelvis. The glands cannot be cleared out in the perineal operation. In making his incision he went clean through from the anus, as he obtained more room. His experience of colotomy was such that he would never perform the operation unless driven to it, for it did not relieve the patient of pain.

The Section then adjourned.

Reviews and Notices of Books.

Practical Manual of Diseases of Women and Uterine Therapeutics, for Students and Practitioners. By H. MACNAUGHTON JONES, M.D., M.Ch., M.A.O. R.U.I. (*Hon. Caus.*), Fellow of the Royal Colleges of Surgeons of Ireland and Edinburgh. &c. Sixth edition, revised and enlarged. London: Baillière, Tindall, and Cox. 1894.

THE author tells us in the preface that in preparing the present edition he has endeavoured to construct a comparatively new book, that much of it has been re-written, re-arranged, and re-illustrated, and that much new matter has been added. To make room in part for such changes he has omitted those chapters on Diseases of the Mammary Gland which hitherto appeared, and has curtailed the space devoted to less important topics. We cannot quite understand from the following passage whether the author means that flexion causes congestion of the uterus, or whether it is the congestion that causes flexion:

"The uterus is thus balanced in the pelvis by the reflection of peritoneum and encircling cellular tissue. Thus is explained the tendency of the uterus to bend backwards and forwards at this situation, a bending still further increased by the consequent constriction of the bloodvessels at the junction of the cervix with the body, and an increase of weight posteriorly or anteriorly from congestion of the tissues in the posterior or anterior wall of the fundus above the seat of constriction. Constriction leads to congestion, congestion to hyperplastic effusion, and both to excessive tissue formation, which ultimately tends to contraction and resulting flexion."

We see that Dr. Macnaughton Jones is still of opinion that flexion of the uterus causes "narrowing or twisting of the uterine canal at this spot, and stenosis with all its consecutive ills."

We notice that the presence of a tenacious plug of mucus in the cervix is regarded by the author as a frequent cause of sterility; also that simple incision of the lower part of the cervix has frequently to be resorted to, and that in cases of sterility where dilatation has failed, in severe endometritis with dysmenorrhœa, and in spasmodic dysmenorrhœa, he advises division of the cervix uteri and internal os after Sims's method, followed by the introduction of an intra-uterine stem pessary. To our thinking much of the above treatment is unscientific. If it cannot be shown to be definitely beneficial there is at least one good reason for avoiding it—namely, that consequences of more or less gravity have not rarely followed the employment of the measures to which we have just referred. In speaking of cancer of the uterus the author says: "The views of Sir John Williams as to the usual limitation of carcinoma to the cervix uteri and the bearing of this pathological fact on the extent of the operative interference indicated in cancer of the uterus are well known; but they are not borne out either by clinical experience or the pathological researches of others, and his deductions bearing on the relative advantages of high amputation or supra-vaginal hysterectomy [we suppose the author means 'vaginal hysterectomy'], in the author's opinion, are unsustainable on statistical, clinical, or pathological grounds." This is a sweeping condemnation of the views of one who is

generally regarded as the highest English authority on the subject in question. We may, however, go further, and say that in our opinion the passage quoted is scientifically incorrect. We believe that in the very large majority of cases of carcinoma of the cervix, if not in all, in which any operation can cure the patient—using the word cure to mean at least three years without recurrence—the supra-vaginal amputation gives the patient as good a chance of cure as vaginal hysterectomy. After reading the passage just quoted it is surprising to find a few pages later that the author actually says that there can be no doubt that up to the present, so far as statistics can be relied on, recurrence has been postponed for a longer period after supra-vaginal amputation, and he refers to statistics which tell in favour of that view. As regards uterine displacements, it is certainly remarkable to find the author saying that he quite agrees with the opinion expressed by Matthews Duncan in his lecture on Minor Displacements, and deploring “the extent to which the charlatanism of pessary adjusters has degraded practice and opened the door for every form of inventive humbug,” while he himself figures, and presumably recommends and employs, a large number of pessaries, including even intra-uterine stem pessaries. In conclusion we feel bound to call attention to, and to strongly deprecate, the somewhat frequent recommendations of various commercial articles which are contained in the work as savouring too much of advertisement.

Lehrbuch der Physiologischen und Pathologischen Chemie In fünf- und zwanzig Vorlesungen, für Aerzte und Studierende. Von G. BUNGE, Professor in Basel. Dritte vermehrte und verbesserte Auflage. Leipzig: Verlag von F. C. W. Vogel. 1894. (*Manual of Physiological and Pathological Chemistry*. In Twenty-five Lectures, for Practitioners and Students. By G. BUNGE, Professor at Basel. Third enlarged and revised edition. Leipzig: F. C. W. Vogel. 1894.)

THOSE who have studied Professor Bunge's *Lehrbuch*, either in the original or in Wooldridge's excellent translation, will warmly welcome a third edition, which has been brought thoroughly up to date. The second edition was divided into twenty-one lectures, but in the book before us a somewhat different arrangement has been made, and separate chapters are devoted to the blood and to the lymph, whilst the chapter in the earlier edition on the nitrogenous products of metabolism has been divided into two. In both these subjects very considerable additions have been made, and as a result of more recent investigations considerable modifications are noticeable in several of the points taken up. Perhaps the most interesting additions of all are the chapters on infection and on fever, and, as one would naturally expect from a consideration of Bunge's earlier lectures, these contain a good *résumé* of these two subjects from the purely physiological, rather than from the pathological, point of view. At the same time we must confess to a feeling of disappointment on rising from the perusal of these chapters, as the numerous facts here recorded have filtered through the author's mind without receiving much of that imprint of originality which characterises so much of the other part of the work, and we cannot help feeling that these two additional chapters form the least instructive part of the work, except in so far as they give a short but admirable account of what has been done. The work in the other chapters has been thoroughly revised, some of the parts have been rewritten, and much new and original matter has been added. Altogether these lectures show that the author has not been content to rest satisfied with the laurels that he gained by the publication of the earlier editions of his book.

Report of the Department of Pathology of University College, London. Vol. IV. Edited by VICTOR HORSLEY, F.R.S., F.R.C.S. Edg., and VAUGHAN HARLEY, M.D. Edin., M.R.C.P. Lond.

THIS volume of reports of original research carried on by various investigators cannot but increase the reputation of the individual contributors for thorough and conscientious work. The papers have already been published in the *Philosophical Transactions of the Royal Society*, and are now issued bound up together for convenience. Most of the investigations were carried out with the assistance of grants from the Royal Society and the British Medical Association. There are five elaborate papers on Neurology. Of these, Dr. Risien Russell contributes two—"Experimental Researches into the Functions of the Cerebellum" and "An Experimental Investigation of the Nerve Roots which enter into the Formation of the Brachial Plexus of the Dog." Mr. Spencer publishes the results of his researches on the Effect Produced upon Respiration by Faradic Excitation of the Cerebrum in the Monkey, Cat, and Rabbit, in a paper which is very fully illustrated by tracings and photographs, and also collaborates with Mr. Horsley in an elaborate paper on the Changes Produced in the Circulation and Respiration by Increase of the Intra-cranial Pressure or Tension. Dr. Beever and Mr. Horsley have continued their minute analysis of the excitable region of the cerebral cortex in the monkey, and give the result of their stimulation of the so-called centres for the facial, lingual, and pharyngeal movements. In the department of pathology a beautifully illustrated paper on Madura Foot by Professor Robert Boyce, and one by Dr. Surveyor upon the Existence of more than one Fungus in Madura Disease (Mycetoma) are given. We congratulate Mr. Horsley and Dr. Vaughan Harley on the issue of this new volume, and on the activity and good management of which it is the outcome.

LIBRARY TABLE.

Organic Chemistry (the Fatty Compounds). By R. LLOYD WHITELEY, F.I.C., F.C.S. London: Longmans, Green, and Co. 1895.—The author of this little work states in his preface "that it is quite impossible to learn organic chemistry properly by reading only." So far we entirely agree with him, and we observe that the preparation of all the simpler organic bodies has been given, but we think that this alone is scarcely sufficient reason for adding another work to the already crowded library of text-books on organic chemistry. We need not remind the author that his work *per se* will not enable the student to obtain a real knowledge of organic chemistry, and that its use in the laboratory, in the face of such works as "Fisher's" and "Streatfield's" Organic Preparations, is considerably lessened, unless the idea is that very elementary students should study only one text-book. We think that such a valuable method as that of Kjeldahl for estimating nitrogen should have had more than ten lines devoted to it, since it has almost entirely superseded the other methods. Also in the section on Alcoholometry the specific gravity method after distilling might have been dwelt upon more fully. With regard to the theoretical portion of the work the author deserves praise for the extremely careful and concise way in which he has dealt with successive portions of the subject.

Therapie der Harnkrankheiten. Von Professor Dr. C. POSNER. Berlin: Verlag von August Hirschwald. 1895. (*Treatment of Urinary Diseases.* By Professor C. POSNER. Berlin: August Hirschwald. 1895.)—This small volume contains the subject matter of ten lectures by Professor Posner of Berlin, and is uniform in scope and character with a similar book which he published last year upon the "Diagnosis of

Urinary Diseases." The subjects are treated in the following order: 1. Acute Gonorrhœa. 2. Complications of Acute Gonorrhœa. 3. Chronic Urethritis. 4. Complications of Chronic Urethritis. 5. Sequelæ of Chronic Gonorrhœa. 6. New Growths in the Urinary Passages. 7. Chemical Changes in Urine. 8. Calculous Disease. 9. Nervous Functional Disorders. 10. Urinary Poisoning. It will be seen that the whole ground is thus fairly well covered, vesical and prostatic affections being treated under the heads of Complications of Urethritis and New Growths. The scope of the work does not admit of the discussion of great detail, but it is written by one well versed in the subject and thoroughly versed in modern practice. As affording a systematised review of the whole subject the lectures are of service, but they fail to display one really valuable character of a work of this class—so conspicuous in Sir Henry Thompson's lectures—namely, a close attention to those practical details which are of most service to the practitioner.

The *Veterinary Journal* for this month contains several papers of interest, among them being the continuation of Mr. Pech's essay on Diseases communicable from the Lower Animals to Man, Dr. Randolph's account of Two Successful Cataract Operations on a Dog, Veterinary-Captain Pease's description of Distomatosis in Cattle, with papers on Pathogenic Bacteria and Albuminuria in Cattle by Mr. Hoare, extracts from foreign journals, and other matter deserving the attention of members of the veterinary profession.

Archives de Neurologie for May. Paris: Bureaux du *Progrès Médical*.—The most interesting part of this number is the case of so-called Hysterical Hemianopsia, by Dr. Pierre Janet. The occurrence of hemianopsia as a hysterical symptom is doubtful, and we venture to think that this case does not furnish any definite or certain evidence on the point. There is a continuation of the article on Intoxication in Epilepsy by Dr. Voisin. Some records of clinical cases and the usual neurological reviews and accounts of meetings of learned societies make up what is on the whole a very interesting number.

Dublin Journal of Medical Science. May, 1895. Dublin: Fannin and Co. The first article in this number is an account of three cases of Friedreich's Ataxy Associated with Idiocy, to which we alluded in an annotation last week. The other articles are on Defective Infantile Life Unrecognised in State Medicine and on Private Hospitals. There are numerous reviews and bibliographical notices and the usual medical miscellany. The number is an unusually interesting and full one.

The Westminster Review.—The marriage question affords matter for the most prominent article in this magazine, and in "Some Modern Ideas about Marriage" E. M. S. pleads that divorce should be no longer synonymous with disgrace. Dr. G. Rayleigh Vicars advocates life-long imprisonment in lieu of capital punishment; and there is an interesting paper on the late Charles Bradlaugh.

The *Veterinarian* for May has also its quota of matter similar to that of the *Veterinary Journal*, though, perhaps, its most attractive paper to other than veterinary readers is the continuation of Professor Ewart's Telegony, in which he indicates the direction experiments should take in order to prove or disprove the influence of the first sire on the future progeny of female animals by subsequent sires. The experiments he proposes would certainly go a long way to demonstrate whether such influence does exist, though it is to be apprehended that some of them could not be easily carried out. Professor Stockman reports a well-marked instance of Tuberculous Lesions in the Muscles of a Pig; and Professors Mossleman and Hebrant of Brussels treat of Osseous Cachexia in Animals. There are also other papers of some value, with

"Abstracted Notes" from various journals, and reviews of books. We observe a startling statement made by the reviewer in his notice of Tegetmeier and Sutherland's work on Horses, Asses, Zebras, Mules, and Mule-breeding. He says: "Considering the many advantages offered by mule labour it is little less than astounding that the present should be the first work on the subject ever published in the English language." It is certainly little less than astounding that the writer of this announcement did not discover that a large portion of the section (for it is only a section) of the book devoted to mules and mule-breeding is made up of quotations from works published in English, while other writings on the subject in our language are not referred to in the book—notably the article in the *Encyclopædia Britannica*, and the chapter in Furze's handbook on Land Transport, where much information is given. At any rate, Riley's work on the Mule, published many years ago, should be known to everyone who attempts to deal with the subject.

Analytical Records FROM THE LANCET LABORATORY.

FERROPYRIN.

(KNOLL AND CO., LUDWIGSHAFEN-ON-RHINE. LONDON: B. KÜHN, 36, ST. MARY-AT-HILL, E.C.)

FERROPYRIN is a dry, bright, chrome-coloured powder, dissolving in water to form a blood-red solution. It is a compound of two molecules of perchloride of iron with three molecules of antipyrin, and is accordingly represented by the formula $(\text{FeCl}_2)_2(\text{C}_{11}\text{H}_{12}\text{N}_2\text{O})_3$. The solution is slightly astringent, but has no corrosive action, while it mixes perfectly with hydrochloric acid, pepsin, potassium bromide, and tannin-free tinctures. The solution yields the ordinary reactions of per-salts of iron, and the antipyrin can be readily detected by nitrous acid, with which it strikes a beautiful emerald-green colour. The object of this interesting and beautiful compound (it is a true chemical combination) is, of course, to be able to administer a palliative analgesic together with a hæmatinic, and the results of its trial in cases of chlorosis, anæmia, and in other conditions where there is blood impoverishment were most satisfactory.

BAKING POWDER.

(ERNEST ALLMAND, 9, HOPE-STREET, WREXHAM.)

It is satisfactory to observe that the list of alum-free baking powders is gradually extending. The above specimen may be justly assigned a place together with those which were pronounced pure and free from alum in the report of THE LANCET Commission on Baking Powders published in our columns on March 3rd, 1894. It yields a satisfactory volume of carbonic acid gas when moistened, and the ingredients are of a purity which is demanded of a preparation that is intended for mixing with food. We hope that the Food Products Adulteration Committee now sitting will be led to recommend shortly that baking powder be included in the Food and Drugs Act, so that proceedings may be successfully taken against those who would "alum" food by this indirect means.

CADBURY'S COCOA ESSENCE.

(CADBURY BROTHERS, BOURNVILLE, NEAR BIRMINGHAM.)

The great and important improvements that have been effected in recent years in the manufacture of cocoa have been largely due to the placing upon the market of standard preparations of the above type, Messrs. Cadbury Brothers being amongst the first to produce a cocoa of satisfactory purity, quality, and flavour, and of easily digestible character.

From the dietetic point of view the removal of the greater portion of the indigestible fat of cocoa is the most important step in the process, which is nevertheless carried to a successful issue without impairing the cocoa in any degree, and so satisfactorily is it done that recourse to objectionable diluents like starch and sugar is quite unnecessary. The quantity of fat eliminated in the course of manufacture is at least two-thirds. On incineration the cocoa yields 4.86 per cent. ash, of which 3.62 parts are insoluble and 1.24 soluble, the alkalinity of the latter being equivalent to 0.44 per cent. potash (K_2O). In connexion with the evidence afforded by a microscopic examination the results leave no doubt of the purity and excellence of this specimen, and the figures relating to the alkalinity of the soluble ash in particular show that there has been no treatment with fixed alkalis, or with ammonia according to other chemical tests. The preparation represents, therefore, the standard of highest purity at present attainable in regard to cocoa.

SACCHARIN.

(GILLIARD, P. MORMET & CARTIER. LONDON AGENCY: R. W. GREEFF & Co., 3, EASTCHEAP, E.C.)

We have received from this new agency a sample of saccharin and a sample of the more soluble sodium salt. The former is marked 500 No. 1, and the latter 300 No. 4, which indicate their respective degrees of sweetening power when compared with cane sugar. The sample of saccharin, which burned completely away on platinum foil, is stated to be free from para-sulphamine-benzoic acid, while the other specimen left a fusible residue which contained sulphate, derived, of course, from the sulphur of the benzoyl-sulphonic-imide. Both are evidently fine and pure products.

New Inventions.

CELLULOID VAGINAL DOUCHE.

THE following relates to a special form of vaginal douche (illustrated below) for which certain important advantages are claimed—viz.: 1. Shape and curve of pipe facilitate

introduction (oval on section). 2. Transparency ensures cleanliness. 3. Unbreakable. 4. Self-retaining (owing to expanded extremity). 5. Inflated adjustable rubber cushion to occlude the vulval outlet. 6. Can be

used by patient herself and is very comfortable in use. 7. It entirely obviates use of drawsheet. No risk of wetting bed. 8. Readily takes into four parts when necessary to clean. 9. Cannot get out of order. 10. May be used with any ordinary india-rubber syringe. 11. Large waste pipe. 12. It may be used simply to irrigate the vagina or to flush out that passage. This latter is done by clamping the waste pipe with the finger and thumb whilst the bulb of the syringe is compressed two or three times. Upon setting free the waste pipe the muscular action of the vaginal walls is at once brought into use to expel the injected fluid (and with it any blood-clots or discharge) from the vaginal cavity through the numerous large apertures in the tube. If only used as a syringe it is superior to those in general use, as the comparatively large celluloid pipe will open out the folds of mucous membrane, and thus give a much better chance of thoroughly cleansing it by means of the injected fluid. 13. With special tube may be used to wash out the uterus. 14. The price compares very favourably with any other apparatus for the like purpose. Messrs. Arnold and Sons of West Smithfield are the agents.

Caledonian-road, London, N.

ROBT. H. RAINS, M.R.C.S.

THE CAMBRIDGE SCHOOL OF MEDICINE AND QUALIFIED PRACTITIONERS.—We are glad to learn that the proposal to hold a week of demonstrations and lectures at Cambridge for the advantage of qualified practitioners is likely to be a success. The time is from Monday, July 1st, to Saturday, July 6th. Mr. Joseph Griffiths of King's College is the hon. secretary. Cambridge shows a sense of the times and of her own duty in such adaptations of her facilities for teaching.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The final examination for the Fellowship of the Royal College of Surgeons has been held this week. It has extended over five days—viz., from Monday to Friday. On Tuesday, 21st inst., the examinations, both written and *visu voce*, on surgical cases took place, and, as usual, many Fellows of the College attended to see the cases which had been collected. A notice was posted in the examination rooms requesting visitors not to approach too closely to the candidates under examination, and asking them also to make as little noise as possible. Probably as a result of this notice the examination rooms were much quieter on Tuesday than on many previous occasions, when, as we mentioned in noticing the clinical examination last November, some of the visitors seemed to imagine that the cases were specially provided for themselves. Many of the cases shown were of very great interest, though we can only mention a few of the more striking. 1. A man aged twenty-eight showing numerous exostoses, especially on the bones of the limbs. They were unusually large. Several other members of his family were similarly affected. He was blind in both eyes; this was attributed by him to injury at the age of fourteen years, but was possibly due to congenital syphilis. 2. A young woman having a firm swelling at the upper end of the left popliteal space. Nine months ago she had had a tumour of one year's growth removed from the back of the left thigh, and three months later the present swelling appeared. It was evidently a sarcoma. 3. An elderly man with a small tumour of the umbilicus; no swelling could be felt in the abdomen, but the growth was probably malignant, and secondary to some abdominal tumour. 4. An elderly woman with an enlargement in the left parotid region of seventeen years' duration; the swelling was very obvious in the mouth, reaching nearly to the middle line, and interfering to a great extent with deglutition. It was probably fibrous in nature, and arose from the tonsil or from the deeper portion of the parotid. 5. A man with a chronic effusion in the left knee, and for three months having had a firm swelling over the right great trochanter; this was probably due to gummatous deposit in the wall of the bursa over the great trochanter; the joint affection was also probably syphilitic. 6. A young man having a swelling in the mesial plane of the neck; it projected below the jaw, but especially extended into the mouth, pushing up the tongue and greatly hindering swallowing. The contents were apparently quite liquid; it was, therefore, probably not a dermoid. The most likely diagnosis seemed to be that it was due to effusion into the bursa between the genio-hyo-glossi.

THE LANCET.

LONDON: SATURDAY, MAY 25, 1896.

THE authorities of the Royal Medical Benevolent College are to be thanked for securing Mr. BALFOUR's presidency at the twenty-seventh festival dinner. It is becoming evident that the public, apart from political proclivities, looks to Mr. BALFOUR as to one of its foremost guides in deep matters of thought and feeling. In his speech at the dinner we get a glimpse into his estimate of medicine, its claims on the public regard, and its most essential functions. Like Mr. GLADSTONE and Lord SALISBURY he has thought much on the subject and his conclusions are not uncomplimentary to the profession. In company with most speakers he recognises the amount, the lavishness, of its gratuitous or ill-paid work—the skill and the time given, often by its most meritorious members, to those who cannot recompense them. And on this fact he founds his claim for the greatest medical charity of our country, one that provides for the widow or the orphan—pension or foundation scholarship—of those who in the very nature of the sphere or the circumstances in which they worked, or of the time they had to work in, had not the opportunity to “provide for their own house.” The work of the profession is done very much in secret. What agonies undreamt of by the public does not the hospital surgeon or physician relieve? And the general practitioner in a poor district is not one whit less beneficent as he carries his help and his counsel to the houses of the poor in their extremities of suffering, and in doing so often lays the foundation of his own disease. It would not be unreasonable if the charities of such a profession were generously subsidised by the wealthy members of the public. We will venture to hope that the £1700 which were announced at the dinner do not represent the full response to Mr. BALFOUR's appeal.

Not less interesting to our readers than his argument for the generous consideration of the profession by the public is his estimate of our position from a critical point of view. He thinks the debt of humanity to medicine, though large in the past, is increasing and “likely to increase in the future in a rapidly extending ratio,” and this because it is becoming more sure in its methods and in the application of science to its art. “Science and practice are every day more and more joining hands. . . . Medicine is becoming more and more the work of the scientific expert and less the work of the empiric”; and he anticipates not only an “incomparable insight into the nature and cause of disease,” but “an ability to command in a far larger measure than we do now” “the remedies which may be successfully applied.” Such estimates by such a judge may well please the profession. But they have their serious side. They strike at all superficial and careless work, and should stimulate every practitioner to regard with interest as being one to be met with skill guided by science each case he is called to minister to. This is the true line of success—the real way of victory over all pretenders—to get the “incomparable insight” into the cause of each

disease we are called to treat, and in that light to deal with it.

Mr. BALFOUR seems rather afraid that with all its new lights the profession may come to aid longevity too much, especially if men are temperate. As he says, temperance is a virtue which medicine may counsel, but cannot enforce. Undoubtedly the clear message of medicine to men is one of temperance. The want of this virtue will in most cases destroy the best constitution and defy the best surgery and medicine alike. A friend of Mr. BALFOUR's thinks that by more perfect medicine the span of life may be extended to 120 years. It may be so. An old estimate (Ecclesiasticus) gave a man's days as possibly 100 years, and twenty more would seem a slight improvement for over twenty centuries to effect. Mr. BALFOUR in the end of his interesting address suggests that the mere prolongation of life is not one of the triumphs of medicine. He demands of medicine that it shall ease men of pain and that it shall render the allotted life we have more available for work and duty. Given this, he would relieve it of the duty of prolonging a painful and useless life. There is a doubtful ring about this suggestion. It is very difficult to dissociate the function of relieving pain from that of prolonging life. They are practically synonymous. But we cannot admit that even where we cannot relieve pain we are one whit the less bound to preserve and prolong life. “This long disease my life” has been true of many others than POPE who have made great contributions to the happiness of the world. A late physician who did more than most men of his order used to say that he never had a day's health in his life; yet few men enjoyed life more or used it better. There is a charm in life which we should expect Mr. BALFOUR to recognise apart from conditions of perfect ease—

“For who would lose,
Though full of pain, this intellectual being—
Those thoughts that wander through eternity?”

Man is a creature of such possibilities that the prolongation of his life for even a few weeks or months may have great importance, and although “the laws of the realm may punish Christian men with death for heinous and grievous offences” it is not yet recognised as part of a medical man's duty that he should take away that which he cannot give back.

THE oration by Mr. PEARCE GOULD on the Recent Evolution of Surgery was more than a mere domestic event in the history of the Medical Society of London. It was a statement of the nature and significance of the recent development of surgery such as could only be made by an orator who had made some mark both as a teacher and a surgeon. The crowded and representative audience, composed of men in every branch of practice, showed that the subject was one of absorbing interest, and the close and quiet attention with which the address was listened to was the best proof that the orator had succeeded in his object. Surgery is no longer a mere matter of handiwork. It is an object-lesson in which the great facts of physiology, biology, and pathology find recognition. Mr. GOULD's address will have historical interest not only as the exposition of this change, but as tending to give the change great confirmation. Within the memory of middle-aged men the surgeon was little more than a user with marvellous dexterity of knives and scissors

and needles. But the results were not equal to the manipulation. Not only so, the sphere of interference was very limited. Nearly everything beneath the surface of the body was considered out of reach and was relegated to the physician. Now the surgeon runs the physician very closely in respect of knowledge of the fundamental sciences which underlie all successful practice and has that exquisite regard for the peculiar properties of every organ and tissue which had hitherto been credited mainly to the physician.

In all recent expositions of surgery and its progress the introduction of antiseptics has overshadowed all other facts in prominence. Mr. GOULD last Monday night was very successful in avoiding the use of this hackneyed phrase, but, all the same, this fact was the foundation of all that he said, as will appear. His point was to show that something has happened in the development of surgery in the last twenty-five years more important than the ordinary progress of any similar period or of any previous century, "or even millennium." Some may think the proposition extreme; but the steady way in which Mr. GOULD built up stone after stone in its demonstration will leave no doubt that in the main he was right. Progress was not a strong enough word for his purpose. Evolution was preferred. The word in this sense and connexion is open to some criticism. It implies, to our thinking, something essentially progressive, continuous, and even. But it is a part of Mr. GOULD's contention that something has happened in surgery out of the common, expanding and elevating it in every branch and department, and that this has produced *rapidly* a change in the character of all the work done. This is not mere evolution. It is more like revolution. It is, in fact, discovery. Of course, there is a sense in which discovery is evolution; but we do not apply that word to NEWTON's discovery or even to DARWIN's. A grand conception, a pregnant idea, may be regarded as part of a great progress of mental evolution, but the word itself is rather applicable to great, continuous, equable processes in nature affecting organised beings. This, however, is a detail. The excellence of Mr. GOULD's address consisted in the wide view he took of the change that has come over surgery and over the spirit in which it is practised. His analysis of the elements of improvement was as admirable as it was original. The removal of the formerly admitted anatomical restrictions upon surgical operations; the higher anxiety to preserve the physiological integrity of the organism; the essentially conservative nature and tendency of the operations practised under the new system; a higher conception of the nature of surgical operations, of the way in which wounds are to be repaired, and of the personal responsibility of the surgeon for avoiding disasters from his own procedures more terrible than the original disease; the clear apprehension that the causes of disease have to be treated directly; the introduction of what are practically physiological operations into surgery—these are the elements of the great evolution or revolution which would make the practice of any living surgeon unintelligible to a surgeon who practised fifty years ago if he could be suddenly brought back to witness the change. They are ideal changes which raise the spirit in which work is

done, the methods by which it is done, and the results which follow.

Though Mr. GOULD said scarcely anything on Monday night of antisepticism, his tribute to Sir JOSEPH LISTER was the feature of his address. He referred powerfully to the incident of Sir JOSEPH LISTER's paper read before the same society twelve years ago on the direct suture of the fragments of a transverse fracture of the patella, and to the remark of a distinguished junior that such a procedure was magnificent, but was not surgery! And in his peroration he did not hesitate to place Sir JOSEPH LISTER's name in a line with HARVEY's and with JOHN HUNTER's as the one which now shines with an unrivalled splendour on the page of surgical history. This praise is just, and it is not premature. Mr. GOULD was right in emphasising the duty of doing honour to men to whom honour is due while they are alive. Nor is the praise less just because it comes from British lips. It will be echoed from every civilised country. But it was well spoken here. Foreigners will not think the less of us or of him for doing justice to Sir JOSEPH LISTER, to whom more than to any other man we owe the elevation and the advance of surgery, whose methods have introduced safety where formerly all was full of risk, and have had an effect on the comfort of patients after operation which is only less remarkable than the anaesthesia which deprives the operation itself of terror.

THE importance of the discovery of argon, a newly identified constituent of the atmosphere, by Lord RAYLEIGH and Professor RAMSAY is yet to be estimated. Already it has opened up ramifications which have bewildered many of our leading scientific men, some of whom have been led into quite new fields of study of which argon must be regarded as the gate. First came the observation of the eminent French chemist, M. BERTHELOT, that when argon was submitted to the action of benzene vapour under the influence of electrical discharge there was some indication of a combination having taken place, so that not a few began to think that argon—meaning inert—was not a well-chosen name. But the most interesting result of M. BERTHELOT's experiments was the fact that after some time the silent discharge through this mixture became gradually luminous, and the tube was lighted up in almost its entire extent at first with a violet tint with a reddish rain of fire, changing gradually to a splendid green shade visible even in full daylight and recalling in a most striking way the brilliant spectacle afforded in the aurora borealis. Professor RAMSAY followed soon after with the startling announcement that he had found that the gas evolved from a certain mineral (clèveite or uraninite) on treatment with acid was argon and not nitrogen, as had all along been supposed, and that, further, a spectroscopic examination of this gas revealed a bright and perfectly definite yellow line situated between the well-known sodium lines, which left not the slightest doubt that an element hitherto regarded to exist only in the sun (helium) had been set free from a terrestrial mineral. This has since been fully confirmed, and helium has been added to the list of simplicities—so far as we know them to be simplicities,—while

many of its properties have since been ascertained. Professor CLÈVE, however, from whom the mineral derives its name, was unable to confirm the presence of argon; although he expressed no doubt as to the presence of helium. "What makes me most curious," he wrote to Professor THORPE, "is that our helium gas was free from argon and that Mr. RAMSAY's did contain that most curious stuff. Is there any relation between argon and helium, and are we approaching a new epoch in chemistry?" At once there arose a mystery about "clèveite gas," which became still more obscure when Professor NORMAN LOCKYER declared that he had found no argon, but hydrogen. Thus apparently the same clèveite had been tortured (to use Professor DEWAR's happy expression) by three independent investigators into giving up to the first argon with helium, to the second helium with hydrogen, and to the third helium. Could clèveite be the mystic philosopher's stone which in its substance could transform one element into another, so that, according to the condition of experiment to which it was submitted, it gave up and presented to one argon, to another helium, and to another hydrogen? Or does it contain the primary stuff of which all elements must be composed in accordance with the celebrated hypothesis of PROUST, or, later, of Professor CROOKES, and that on extraction it assumed one of those forms known to us as hydrogen, helium, or argon? The idea, however, that we were nearing the transmutation or transformation of elements vanished rapidly into thin air when Professor RAMSAY announced a few days ago that the gas he originally obtained was contaminated with atmospheric argon, but that the gas accompanying helium was none other than hydrogen with traces of nitrogen, so that it transpires that what was originally regarded as nitrogen evolved from clèveite and then argon was after all helium with hydrogen and traces of nitrogen. That, at any rate, is the latest representation of the composition of clèveite gas. It is all the more remarkable that in searching for what Professor RAMSAY thought would most likely turn out to be argon he stumbled upon another element altogether—the long-missing helium. For the present this discovery must be regarded as the most important outcome of the splendid and laborious investigations which led Lord RAYLEIGH and Professor RAMSAY to announce last year for the first time the existence of this constituent in the atmosphere. The possibility of further discovery does not, however, stop here. Professor NORMAN LOCKYER, for instance, who obtained the gas from the mineral by heating it in vacuo—a method he uses for the extraction of gases from meteoric stones,—is led to suggest that the gas is one of complex origin, and spectroscopic analyses show distinctly that several lines in clèveite gas are closely related to the solar and stellar phenomena. "We appear to be in the presence of the *vera causa*," he writes, "not of two or of three but of many lines which so far have been classed as 'unknown' by students both of solar and stellar chemistry; and if this be confirmed we are evidently in the presence of a new order of gases of the highest importance to celestial chemistry, though perhaps they may be of small practical value to chemists, because their compounds and associated elements are, for the most part, hidden deep in the earth's interior."

It will be readily realised that the interest created by

these observations is intense, and we can imagine the scientific thinker drawing a deep breath in almost feverish expectancy that before very long a portion, at any rate, of the veil which keeps many of the cosmic mysteries from our view will be drawn aside. Then we shall indeed attach some importance to Lord RAYLEIGH's and Professor RAMSAY's joint discovery.

THERE was a time, not very remote from the present, when complaints were frequently made of the tardiness with which the national returns of birth and death were issued from the General Register Office—the more important of these returns, up to a recent date, having been rarely available to the public until nearly two years after the expiration of the period to which they severally related. Having regard to the vastly greater interest which nowadays attaches to the official mortality returns of Somerset House in consequence of their direct bearing on the question of local sanitary administration, we are glad to note that the publication of the Registrar-General's quarterly and annual reports and returns has of late been considerably expedited; and as this has been accomplished without, we believe, any addition to the official staff we regard the event as highly creditable to the Statistical Department. For it is obvious that so far from the work becoming lighter as time goes on the number of facts to be dealt with in successive reports increases year by year, almost *pari passu* with the growth of the population. The circumstance which has suggested the above remarks is the publication within the last few days of the Registrar-General's Annual Summary for 1894, which gives useful information respecting the mortality that prevailed amongst a considerable portion of the population of England during the fifty-two weeks of that year.

Originally the annual summaries had exclusive reference to London and a few of the larger provincial towns. The present summary, however, relates to 100 of the most important urban communities of England and Wales, including, of course, the metropolis; and with respect to many of these areas the information given is more extended, and for local sanitary purposes far more serviceable, than any that has hitherto been accessible. In addition to the thirty-three great towns included in Table I., full mortality statistics for which have been published in the periodical returns for the last few years, corresponding information is now for the first time given in Tables V. and VI. relating to sixty-seven other English and Welsh towns, which, although of less size than the thirty-three chief towns before referred to, are, nevertheless, of considerable importance and contain amongst them an aggregate population of more than three and a half millions. Many of these towns are either sea-side or inland health resorts, and consequently an authoritative statement concerning their death-rate, and especially their mortality from infectious disease, cannot be otherwise than interesting and serviceable to intending visitors.

Another new feature in the recently issued summary which is worthy of attention is the introduction into Tables H. and I. of a column giving the distribution of the corrected mortality from phthisis in each of the five groups of sanitary areas into

which the metropolis is divided for statistical purposes. In Table H. the deaths from phthisis are given in the several sanitary areas of London, but in view of the uncertainty attaching to estimates of population for areas of this kind we think that the Registrar-General has acted wisely in abstaining from the publication of rates of mortality for populations smaller than the five groups of sanitary areas which are comprised in Registration London. When the census of next year shall have been completed we shall hope to see a table published in due course similar to the one now given (Table I.), but dealing with individual sanitary areas, and giving, on the secure basis of the census figures, the rates of mortality not only for phthisis, but for the other diseases also which are at present included in the table referred to. Another table, which we notice for the first time in the present annual summary, is the one marked C. on page viii., which shows the deaths from influenza registered in each of the metropolitan sanitary areas in the five several years 1890 to 1894, practically the period covered by the epidemic, which has even now scarcely come to an end. Yet another new table (E.) will be found at the foot of page x., which gives the admissions and deaths at the Metropolitan Asylums Board Hospitals, the Highgate Small-pox Hospital, and the London Fever Hospital of persons suffering from small-pox, scarlet fever, diphtheria, and enteric fever respectively. The admissions and deaths are given for the ten years 1885 to 1894, and are extremely interesting as showing a rapidly increasing tendency on the part of the public to avail themselves of public hospitals for the treatment and isolation of the infectious sick. It is necessary, however, to utter a word of warning against the acceptance of the figures in this table as being in any degree an accurate measure of the amount of infectious sickness actually present at any given period in the metropolis. It is well known that whenever such a disease as, for instance, scarlet fever becomes seriously epidemic in London the hospitals speedily become filled with cases of that disease, and thus no available space remains for the accommodation of other and not less infectious forms of fever—diphtheria, for example, which disease, as is pointed out in another part of this interesting summary, has been steadily making headway in London for several years past. As far as may be judged by the mortality statistics of the 100 great towns, the health of England and Wales during the year 1894 was, on the whole, eminently satisfactory. For instance, the thirty-three principal towns, which contain an aggregate population of more than 10,000,000, showed a death-rate of 18.1 per 1000 only, against an average rate for the ten previous years of 21.3. London was subject to a mortality not exceeding 17.8 per 1000, or 2.6 per 1000 below the average; and many of the other great towns showed a decline even greater than these. Turning to the figures for the sixty-seven smaller towns, now published for the first time, we are struck by the extreme lowness of some of the rates. The 3,500,000 people inhabiting these towns died in 1894 at the average rate of 18.0 per 1000. Amongst these towns not one had a rate exceeding 22.1 per 1000, whilst the rates were as low as 9.5 per 1000 in Hornsey, 10.0 in Bourne-mouth, and 10.3 in Eastbourne.

Annotations.

"Ne quid nimis."

THE MEETING OF THE GENERAL MEDICAL COUNCIL.

THOUGH we are writing before the issue of the programme of business at the approaching meeting, we cannot be wrong in assuming that the subjects to be discussed will be of varied and considerable interest. One change in the *personnel* will be felt as well as seen. Sir John Simon will be conspicuous by his absence. It must, however, be admitted that his successor will be a real acquisition to the Council. Considering the importance of questions of State medicine and the multiplication of medical officers of health, it would have been unsatisfactory had any less authoritative exponent of the State interests in sanitation than Dr. Thorne Thorne himself been appointed to succeed Sir John Simon. Some other day when a Crown vacancy occurs the State may generously give it to a general practitioner, as it has done before in the case of Scotland, but all must allow that Sir John Simon's successor is well chosen, the more so as a chief feature of the business will be the discussion of reports on Diplomas in State Medicine. It is expected also that a general report on the recent inspections of examinations will be received from the Examination Committee. It would be sanguine to expect that sundry cases of alleged misconduct will not occupy a considerable part of the time of the Council. The subjects of the Midwives Registration Bill and of the issue of certificates to midwives by the Obstetrical Society and other bodies will necessarily come before the Council. At the last meeting, as the minutes of 1894 show, a report was expected from the Executive Committee on the proposed amendments of the Medical Act, but it was not forthcoming. Doubtless it will appear next week. The fate and future of the Apothecaries' Society of Dublin will have to be considered and determined by the Council. Perhaps the most important question of all is the fixing of final arrangements for the issue of a new edition of the Pharmacopœia, about which considerable difference of opinion exists. Our readers may like to know that the Council will commence its meeting on Tuesday next at two o'clock with an address by the President, Sir Richard Quain.

A CASE OF ALLEGED PREMATURE BURIAL.

UNDER the sensational heading "*Le Cauchemar*" we read in *Le Petit Journal* the most recent case of alleged premature burial. It is copied from Greek newspapers, and alleges that the Italian Consul at Mersina, in Turkey in Asia, the name being given, died the week before last, the word "*mort*" being in italics. The funeral took place with much pomp and ceremony, all the foreign consuls and local authorities being present; the burial took place at the Roman Catholic cemetery of the town. That same evening one of the keepers of the cemetery, so runs the story, heard cries coming from the vault just closed. Seized with terror, he ran to forewarn the family. They hastened to the cemetery, and the coffin was opened. Then follows a harrowing description of what was seen; which need not be repeated since the appearances were such as would naturally result from decomposition, and to the eyes of terrified laymen accepting implicitly the story of the alleged cries would present all the supposed phenomena of premature burial. No mention is made of the nature of the last illness or of the cause of death, nor are we told what followed upon the alleged frightful discovery. As the deceased was a Roman Catholic it may be assumed that he had the services of a priest up to the last, and it is impossible to believe

that he, with all the other attendants, relatives, friends, medical practitioner, undertaker, &c., should be deceived. Again, although the interment in foreign countries takes place within an interval which, to English ideas, seems very short, it is for the very reason which the writer of the article gives as the only reason which justifies interment—viz., putrefaction. This in many countries is so rapid as not only to justify, but to render imperative, burial within twelve hours, and in England most medical practitioners can call to mind cases where the closure of the coffin has been required within a similar or even shorter period. In some cases, by no means few, decomposition of some parts of the body may be said to precede death. But nothing that has been published has yet disproved the fact of death being perfectly ascertainable. Sir Francis Seymour Haden in urging burial within thirty-six hours of death dismissed the alleged difficulty of premature burial with the remark that the words of a witness "I knew that he was dead" were generally accepted without dispute. There was a case published in THE LANCET not long ago¹ in which an elderly woman was laid out before death had actually taken place. Then there was the alleged case at Newcastle of apparent recovery from death, which was contradicted, and other cases, which all go to prove the rule that death is not a matter requiring skilled evidence, but is in the large majority of cases a fact evident to the meanest capacity. Every day persons are taken to hospitals, arriving there at the last gasp or actually dead. It is necessary to give a decided answer, since the person, if living, must be conveyed to a ward or continue to receive attention where he or she is. If, on the other hand, death has taken place, the body must obviously be taken to the "dead-house." It may be confidently asserted that such a criminal mistake as sending a living person to the mortuary has never been made; it would, indeed, be unpardonable with medical men on the premises. But these are only a very small proportion of the total number of deaths, the large proportion of which occur in the homes of the rich, the poor, and the middle classes, in presence of laymen and laywomen. The fact of death can very rarely be a matter of doubt, and in such case it is inconceivable that burial would be permitted. It is high time that the editors of all papers which wish to be considered respectable should refrain from publishing stories which can serve no good purpose, and we trust before long to learn that this most recent one has been proved to be a fiction.

IMPROVEMENTS IN THE TECHNIQUE OF THE DIPHTHERIA CULTURE TEST.

A USEFUL modification in the mode of practising the culture test for diphtheria is described by Dr. Ohlmacher in the *Medical News* of Philadelphia of May 4th. He draws attention to the fact that when the culture test was used for sanitary purposes alone the amount of time consumed in the bacteriological examination was of no great moment, but with the advent of the antitoxin treatment of this disease an entirely new era of usefulness for this test was inaugurated. In the best of existing methods it is necessary to allow an interval of from twelve to eighteen hours of incubation to elapse before a tube culture inoculated with the material from a diphtheritic throat can be examined bacteriologically. This length of time is naturally a disadvantage. As is well known, it is customary for observers to wait until visible colonies of the bacteria appear upon the surface of the culture medium before a microscopic examination is made. Dr. Ohlmacher has adopted another method, which promises to be successful. A tube of Löffler's serum culture medium, prepared after the modified or American method of

rapid coagulation, with a smooth, moist, slanting surface, is inoculated with the exudate from the suspicious throat secured with the aid of the Prudden swab. It is of prime importance that the slanting surface of the culture medium should be both perfectly smooth and moist; and care should be taken not to injure the surface of the serum as the cotton swab is rubbed gently but thoroughly over it. As soon as the inoculated tube is received at the laboratory it is placed in the incubator, the temperature of which is 37.5° or 38° C., where it remains undisturbed for four hours. At the end of this time a thoroughly sterilised platinum loop is gently rubbed over the smooth surface of the culture medium, and then the loop is rubbed into a minute drop of distilled water placed in the centre of a clean and sterilised cover-glass. In this way the material obtained on the loop is washed into the drop of water, and while no visible accumulation will have been observed on the loop an examination of the drop of water with a proper illumination will reveal it to be distinctly cloudy. The drop of water is now evenly spread, by the use of the loop, over a limited area of the cover-glass. This spreading is also of importance, since an extensive application would separate the bacteria so widely as to render subsequent examination difficult. As soon as the film has dried, the cover-glass is passed three times through the flame and then stained. Dr. Ohlmacher prefers methyl-violet as a stain for the diphtheria bacillus. A specimen prepared in this way will, upon examination with the microscope, reveal the diphtheria bacilli, provided the case be one of true diphtheria, or it will show the micrococci of false diphtheria. The number of bacteria in one of these early preparations is, as a rule, not great; but no trouble will be experienced in finding plenty of organisms upon which to base a satisfactory diagnosis if the investigator is thoroughly familiar with the morphological characters of the various bacteria encountered in the culture test.

BOARDS OF GUARDIANS AND NURSING.

IT cannot be gainsaid that the circular issued at the beginning of the year from the Local Government Board upon workhouse administration has been the means of discovering numberless defects in the treatment of the sick poor in many of our workhouses. One somewhat notable instance has occurred in south-west Sussex, and reference has already been made to it in THE LANCET.¹ The absolute necessity of a supply of good nurses was the keynote of the circular, and the board of guardians at the workhouse in question, acting upon these instructions, appointed a head nurse and two assistant nurses from a nursing institution in Surrey. The result was deplorable to the guardians, inasmuch as the condition of things in the infirmary and the other part of the house as brought to light—and very properly, too—by the nurses astounded every member of the board. The visiting committee have since that time gone fully into the matter, and at the meeting of the board last week presented a most exhaustive report. The three nurses had already returned to their institution by the mutual consent of the guardians. "The committee," the report states, "were of opinion that although there was room for improvement, yet that matters had been exaggerated." The report is full of recommendations, and the principal, perhaps, is that the nursing arrangements should be placed under the entire management of the medical officer, it being thought that by so doing a better state of things will prevail in the future. The guardians were very fortunate in having amongst them on the day the report was submitted Mr. J. S. Davy, one of the inspectors of the Local Government Board. He gave the board some very valuable advice. He pointed out that the recommendation of the committee that the medical officer should appoint the nurses

¹ THE LANCET, Feb. 2nd, 1895.

¹ THE LANCET, April 13th, 1895.

was not in any way novel or in any way an ordinary practice at well-managed workhouses. As to the number of nurses, he warned the board against setting up a mere numerical proportion of so many nurses for so many sick; they must have a definition of what was meant by "sick," and of that the medical officer was the only judge. The medical officer's duty was so to place his views that he might discharge his responsibility adequately before the board of guardians, and it was the duty of the board of guardians, Mr. Davy added, not to accept those recommendations blindly, but to most carefully consider them with a very considerable bias in favour of adopting them. Other important points touched upon by Mr. Davy were the desirableness of the board becoming acquainted with the conditions that the nurses who will be appointed will be under to the home or institution from which they come, and the danger of making the workhouse nursing of the sick too attractive, whereby not only would patients come in who would never dream of entering the workhouse, but in time great injury would be done to the voluntary hospitals. Such advice can be taken as coming directly from the Local Government Board, and the many boards of guardians that at the present time are considering this question will do well to take heed of the advice given. The report of the visiting committee is to be placed in the hands of all the guardians for a month's consideration before they are called upon to adopt it in its entirety or with modifications. The latter course will no doubt be carried out.

THE ORIGIN OF CHOLERA IN MECCA.

IN 1893 the widespread prevalence of cholera in Mecca had its beginnings in the cases of certain Turkish soldiers who had arrived from the Yemen, where the disease had for some time past prevailed. This year it has had much the same beginning, Turkish soldiers being again the first victims, and this at a date which precludes all possibility of the disease having been imported by sea from India. The onset of cholera this year has occurred many weeks before the Haj, whereas it generally begins just before or during the period in question, and after the arrival of the caravans by land and by sea. The occurrence of cholera in English pilgrims amid the dirty and neglected conditions of the quarantine island of Camaran has had no connexion with the occurrence at Mecca, for the first cases in the latter city took place whilst the unfortunate pilgrims, who, though healthy, had been compelled to quit the pilgrim vessels *Mohammadi* and *Zobeida* for the hovels or huts of Camaran, were still in quarantine on the island. According to the *Times*, M. Henri Monod, at a recent meeting of the Comité Consultatif d'Hygiène of France, blamed England and her refusal to ratify the Paris Convention for this year's cholera at Mecca; but he should remember that if France would only give up her quarantine notions in the Red Sea, as she has begun to do in the Mediterranean, the way of England to do that which is right would be much clearer. It is quarantine in the Red Sea that endangers the lives of Indian pilgrims and constitutes the main, if not the sole, danger of cholera reaching Mecca by way of the sea. If our pilgrims were only allowed, when certified after a long voyage to be free from cholera, to sail on to Jeddah the danger of cholera travelling by the sea route would practically be at an end. Turkey objects to this; sanitary fees and dues are a matter of importance to her local and even central administration, and it is the proposals submitted by France and her delegates to maintain the quarantine system in this part of the world that largely prevents the adoption of sounder principles. We are not pretending here to endorse all the reserves of Great Britain as regards the Paris Conference, neither do we assume that the altered action of France as to quarantine in the Red Sea

could get rid of the major danger of the transport of cholera to Mecca by land routes, whether from the Yemen or elsewhere; but we are convinced that so long as France is guided by those who still cling to old remnants of the antiquated quarantine system under the new name of "observation," so long will the real remedies against cholera be delayed. What is the use of expecting Turkey to spend vast sums on the prevention of cholera in her towns and holy places so long as leading and intelligent nations are always advocating the alternative of quarantine, an alternative which has the immense advantage of helping to fill the somewhat empty coffers of the principal State concerned and those of its local chiefs and officials? M. Henri Monod is, we believe, one of the leading advocates of sanitary measures as such for the prevention of cholera. If he would convert his colleagues to his own views this country would have much less difficulty in uniting with France for the prevention of cholera.

THE IMMIGRATION OF FOREIGN LUNATICS.

IN a letter to the *Morning Post* of May 10th Mr. W. H. Wilkins remarks on the hardship inflicted upon those countries in which are situated ports at which foreign immigrants land in having to maintain those foreigners who are found to be destitute or insane, or both. The landing of foreign insane paupers, who almost immediately go to swell the numbers in our county asylums and have to be maintained at the county's expense, is a matter which should surely be inquired into by the Government, and probably the extent to which the hospitality of this country is abused in this direction could be easily ascertained by the combined action of the Commissioners in Lunacy and the various boards of guardians. Provision is made in the Lunacy Act of 1890 for the return to his own country of any foreigner who is detained in an asylum and whose family or friends desire that he should be removed thither, but there is no provision for the compulsory return of a foreign pauper lunatic. It seems hardly necessary to urge that some such plan should be adopted to meet the case of a foreign immigrant who is found to be insane on, or shortly after, his arrival, and the time of Parliament would be well occupied with the consideration of some such measure of social protection.

HOME OF PEACE FOR THE DYING.

WE have received an appeal on behalf of the Home of Peace for the Dying, to which we gladly give insertion. The history of the institution is briefly as follows. In 1885 a lady, being deeply impressed with the want of any special provision in London for dying men, founded, at her own cost, a small hospital of ten beds in the north of London, which she carried on until the applications so exceeded the accommodation that eight or nine were refused for every one admitted. She then, with the aid of the present council, removed to a large mansion in its own grounds opposite the Swiss Cottage, N.W., which was bought and thoroughly adapted for a large home hospital by a competent hospital engineer. The sum required was £10,000 in all, of which £8000 were raised, and at this very moderate cost *Friedenheim* was opened, with forty beds, by their Royal Highnesses the Duchess of Teck and the Duchess of York on Nov. 7th, 1892. It is the first and oldest charity in London which is solely set apart for men and women in the last stages of illness. Immediate admission is granted solely on the merits of the case, no letters or votes being required, and all diseases, including cancer, being admitted. The charity is administered with the utmost economy, the foundress and lady superintendent accepting neither board nor salary from the funds. Nevertheless, £2000 are urgently required before July 1st to place the finances on

a sound basis. The dying are surrounded with personal care and with every comfort, the nursing staff being full and efficient. This hospital does not advertise, employs no canvassers or collectors, and is entirely dependent upon the spontaneous support of the public in response to the important and almost unique work it carries on. Many distressing cases but for this charity would die unrelieved, the class it reaches being those not suited to infirmaries and yet too hopeless for admission to, or retention in, the ordinary hospitals. Donations and subscriptions may be sent to the bankers, Messrs. Barclay, Bevan, and Co., 54, Lombard-street, or to Miss Davidson, hon. sec., "Friedenheim," Upper Avenue-road, Swiss Cottage, N.W.

THE CASE OF DR. CORNELIUS HERZ.

THAT the course of justice should be tempered with humanity is generally admitted; yet it is apparent from the letter addressed to us by Mr. McHardy and published in another column that this first principle of social ethics may be overborne by political exigencies. It is not too much to say that the treatment of Dr. Cornelius Herz as an "extradited prisoner" is a reproach to the boasted civilisation of two foremost nations. The unfortunate object of this legal persecution has been for the past two years confined to his bed by a mortal illness, which has been gradually advancing towards its inevitable termination; and yet during the whole time he has been kept under police surveillance and has been practically condemned unheard. Surely no course could be better calculated to hasten the end of a sufferer from advanced cardiac disease complicated with diabetes. Mr. McHardy does not hesitate to affirm that this harsh dealing under legal authority is due to the influence of interested persons, whose reputations would suffer if Dr. Herz regained his liberty. He would hardly have ventured to make such a statement without being in a position to prove its truth; and, this being so, it is certainly surprising that the Government of a free country should have been content to be made the cat's paw of a clique, to whose interest it is that the sick man's mouth should be kept closed.

AN OUTBREAK OF MILK-BORNE ENTERIC FEVER IN LANCASHIRE.

MR. EDWARD SERGEANT, medical officer of health to the Lancashire County Council, has recently issued a interesting account of an outbreak of enteric fever which occurred at Great Harwood, and which was traced to the consumption of specifically polluted milk. There were altogether eighty persons, belonging to forty-nine families, attacked, the sanitary conditions of the houses invaded being neither better nor worse than those of other houses remaining free from attack. The water was exonerated from suspicion, since other districts supplied from the same source were not invaded; and there seems to have been no reason to suspect the local pollution of any one water main. So much for the negative evidence. From the positive standpoint it was ascertained that the disease was confined to houses consuming milk from a particular dairy, and that of the houses so supplied no less than one-third was invaded. It was further demonstrated that habitual drinkers of raw milk were attacked more virulently and with greater certainty than those persons who took the milk in tea or coffee. One patient is reported to have attributed his illness to a single glass of raw milk which he took two days prior to his attack. This is certainly a remarkably short incubative period for enteric fever. The question of bovine infection was naturally gone into, and a veterinary surgeon called in to inspect the cattle. The temperature of all the animals was found to be normal, and no eruption on the teats or mammary glands was observed. By carefully inquiring into the distribution of the milk

Mr. Sergeant concluded that it must have become polluted during the process of milking, and it eventually came to light that a young woman who assisted in milking the cows, and who looked after the cleansing of the cans, had since and for some time prior to the commencement of the outbreak felt unwell, but as she imagined herself to be suffering from a cold only she continued at work. On being examined by Mr. Sergeant, Mr. John Patchett, the medical officer of health, and the Chairman of the Sanitary Committee, Dr. Cran, the girl was found with a coated tongue, a pulse of 108, a temperature of 100° F., and a few days afterwards rose-spots appeared on her body. Mr. Sergeant is of opinion that the case was probably one of ambulatory enteric fever, and that for a month the girl has been unconsciously capable of imparting the disease. The conditions observed he regards as a relapse, and that it was not improbable that she was instrumental in imparting the specific properties to the milk; and the fact that the decline of the outbreak, allowance being made for incubation, coincided with her withdrawal from the dairy operations certainly lends considerable weight to this view. That the disease was spread by specifically contaminated milk seems to have been demonstrated, and the thesis that the girl in question had prior to her medical examination suffered from enteric fever is one which would explain the outbreak, more especially if diarrhoea was one of her symptoms.

THE CARE OF YOUNG IMBECILES.

ONE of the recognised defects of our highly organised social fabric is the want of due provision for feeble-minded or idiot children of the humbler classes. Parents sometimes have an exceptional partiality for such of their offspring as exhibit mental defects in a minor degree, and encourage themselves with the hope that the backward little one will improve and grow brighter as years advance. When, however, the condition is more pronounced and associated with bodily deformity and a total inability to acquire cleanly habits, a heavy burden is laid upon the parents, and serious injury may be done to other children by constant association with the afflicted one. In London ample and satisfactory means are provided for the treatment of these unfortunates through the operation of the Poor-law, and in some lunatic asylums idiots are admitted at a comparatively early age, but on the other hand there are extensive districts where such measures of relief are unattainable. The necessity for institutions accessible to the imbecile children of the poor has just been impressed on us by a communication from a correspondent in a Sussex village, describing a painful case and anxiously inquiring if there is no means of relieving a respectable labouring family of the task of rearing an idiot girl five years of age, who can neither walk nor talk, and requires more attention than the state of the mother's health enables her to bestow. Our correspondent, who sympathises with the parents, has made inquiries in various quarters on their behalf, but hitherto without result.

HOUSEHOLDERS AND SANITATION.

A QUESTION of equal interest to owners of house property and to their tenants was decided in court last week. The plaintiff, who, acting upon the assurance of an agent, had taken a furnished residence at Sandgate, attributed a sore-throat and other illness afterwards occurring in his family to damp and effluvia due to insanitary conditions. Evidence was adduced for and against this theory, and a verdict was finally given in favour of the defendant. The case, into the merits of which we do not enter, is, as we have said, doubly instructive. It ought to emphasise a necessity always incumbent upon tenants on making a change of residence—namely, that of providing for thorough inspection of all sanitary arrangements in a

new abode. Such forethought, unfortunately, is not too common, and this is the more to be regretted since the services of a qualified inspector can be readily obtained and at small cost, while the consequences of an oversight in regard to this matter may be serious in the highest degree. House-owners on their part will find that it is true wisdom and true economy in the end to test their property periodically, with a view to its timely repair.

THE MEDICAL SOCIETY OF LONDON.

THE annual conversazione of the Medical Society of London, held on Monday last in the society's house in Chandos-street, was exceedingly well attended, and passed off with much *éclat*. At the close of the eloquent and inspiring oration delivered by Mr. Pearce Gould, to which fuller reference is made in another column, a hearty vote of thanks to the orator was carried by acclamation on the motion of Mr. Clutton, seconded by Dr. Ord. The President, Sir W. Dalby, then received the guests and Fellows, and the rest of the evening was spent in the usual pleasant manner of these agreeable unions. A well-chosen selection of music was performed by the Bijou Orchestra during the conversazione.

THE PSYCHOLOGY OF ANÆSTHESIA.

IN our issue of March 23rd we published an interesting letter from Dr. George Wyld dealing with the psychology of anæsthesia. In another column we give the experience of a contributor when under the influence of both chloroform and ether, but we doubt, as we remarked when commenting on Dr. Wyld's letter, whether dreams during anæsthesia have any sound psychological bearing. The average dream is of no more value as a factor in experimental psychology than Dean Swift's famous dream: "'I have desired Apronia to be always careful, especially about the legs.'..... You must know I dreamed it just now, and waked with it in my mouth."¹ It would be difficult, we fancy, to draw any deduction as to mental processes from this, and we think it is perhaps well to think of all dreams, whether induced by drugs or occurring during natural sleep, as coming "through the ivory gate."

DIPHTHERIA IN LONDON.

DIPHTHERIA in London last week showed a fatality higher than in any like period for some months past. But not alone in last week was there increase in the fatal form of the disease, since the deaths have been rising in number from the week ended April 20th, in which they were 30; the totals in the succeeding weeks having been 27, 29, 38, and 41 respectively; and the corrected average for the similar weeks of the preceding decennial period was exceeded in the last two weeks by as many as 9 and 12 respectively. And whilst the deaths have thus increased in number, the per case mortality has shown a similar rise, for whereas in the two weeks ended May 4th the mortality was some 18.6 per cent. of attacks, it was over 26 per cent. in each of the weeks of the last fortnight. Admissions to hospital, which had been in the previous three weeks fluctuating somewhere between 47 and 50 per cent. of the cases, were last week somewhat over 55 per cent., and the actual admissions, which had been 69, 79, and 73 in successive weeks, were last week 84. The Registrar-General tells us that in the week ended May 11th, 4 cases belonged to opar, and 3 each to St. George Hanover-square, Bethnal Green, Whitechapel, and Camberwell sanitary areas; and that last week the last-named area had 8 deaths credited to it and Islington parish 4 deaths. In these respective weeks the numbers of deaths occurring at

the age-periods one to five and five to twenty, were 20 and 10 and 30 and 7, or at both periods together 79 and 90 per cent. of the whole respectively. In the first of the two weeks there were no fewer than 10 deaths registered from diphtheria in the West Ham district, where the disease seems to be becoming endemic, more particularly in the Plaistow subdistrict. In the London hospitals at the close of last week the number of patients remaining under treatment for diphtheria was in excess of any recorded since Saturday, Feb. 23rd, when the total was identical—namely, 486, the totals of the preceding weeks ended May 11th being 432, 457, and 464 respectively.

"A MATTER OF ETIQUETTE."

UNDER this heading we commented in our issue of April 20th upon the relations existing between Dr. F. J. Waldo and the vestry of St. George's, Southwark. In another column we print an account of the proceedings, up to the present date, from the pen of Dr. Waldo, in the form of a special report from him to the vestry. This report has, we understand, been submitted to the Local Government Board.

PREJUDICE AND EXAGGERATION.

ABOUT a month ago our New York correspondent related particulars of two cases of diphtheria, which terminated fatally after the use of antitoxin. Most of our readers must have felt that the cases, as given, were not conclusive in respect to the allegation that the injections were responsible for the result, in spite of the statement of the physician administering them, who is reported to have said that some mistake must have been made in the preparation or bottling of the remedy. Indeed, in one of these cases it is clear that the patient was obviously dying from diphtheria itself when resort was had to antitoxin. The record has, however, been seized upon by a Mr. Ernest Bell, who has disseminated it broadcast in a letter which has been inserted in a large number of provincial papers, and this writer has the effrontery to say that "similar fatalities" are being heard of "from all sides." We venture to affirm that there is no justification at all for such a sweeping assertion, but, on the contrary, that already there is abundant proof that the remedy has had a surprising influence in diminishing the mortality from diphtheria. The attempt to excite prejudice by such exaggerated statements cannot be too strongly reprobated, and we can only express astonishment that they should have been accepted without demur by those who are responsible for the guidance of public opinion.

A SAFEGUARD FOR INFANT INSURANCE.

POLITICAL rivalry finds no place where the object of legislation is a measure so needful, so impartial, and so purely humane as Sir Richard Webster's Bill relating to the insurance of children. The Bill, which was read second time in the House of Commons on Wednesday last, pursues a course very similar to that recommended by the Select Committee on Friendly Societies, whose report was issued in August, 1889. It accordingly provides for the maintenance and encouragement of the mutual benefit principle in effecting insurances, and it limits the sum insured to an average amount almost as low as that of the friendly societies (£2 up to ten years of age). It entails upon medical practitioners the duty of inquiring as to the fact of insurance before granting a certificate of death, and a like service is required of the registrar. It allows a child to remain under the protection of this Act until sixteen years old. The significance of these provisions may be

¹ Journal to Stella, Letter xv.

judged from what we already know of the terms and the methods allowed by various societies not organised by workmen for their mutual benefit. As regards the former we are aware of no limitation, except the inability to pay the required premium; an average of £4 and a maximum of more than twice this sum are not uncommon; while payment in some clubs is made partly in spirits. It is significant also that wilful neglect of infants, according to a recent return, has been shown to be much more common under the non-mutual system.

THE WOMEN'S LIBERAL FEDERATION AND THE MIDWIVES BILL.

THE members of the council of this association have been discussing the Midwives Bill. A resolution by Lady Carlisle was adopted to the following effect:—"That, as the absence of any State classification of midwives leads to the practice of midwifery by unqualified and incompetent women, and is therefore fraught with extreme danger to the lives and health of both mothers and their infants, this council heartily supports the principle of the Bill for the Registration of Midwives which has just passed its second reading in the House of Lords, and urges Her Majesty's Government to give its support to the same." Lady Carlisle argued in favour of raising the standard of midwives to that of sick nurses. To the objection that if the standard is raised the article will become too expensive, she replied that she looked forward to the time when sick nursing, including, we suppose, midwifery, would be paid for out of the rates, and, like education, be free. She crowned this opinion with the argument that child-bearing was a national service. We are getting on. If child-bearing is to be rewarded as conferring a national favour we shall have even more than plenty of it. Another lady, Mrs. Stanton Blatch, said that when medical men were sent for to attend women of the working classes they sent their unqualified assistants. If ladies wish to make the passing of a Midwives Bill impracticable they will do well to multiply such loose arguments and statements as the above.

On Friday, May 17th, that distinguished cricketer, Mr. W. G. Grace, who is a member of our profession, scored 288 runs for Gloucestershire against Somersetshire. This is in itself a remarkable feat of physical skill and endurance in a man well over forty, but when we consider that this innings was the hundredth occasion of his making a score of 100 runs and upwards the marvel is increased. "Vixere fortes ante Agamemnona." Many another hero has won fame in the cricket field, but we think that this feat of Mr. Grace puts him in a position very far above any of his predecessors or contemporaries, and as the organ of his profession we gladly add our quota to the praises which men of all classes are showering on his prowess.

WE note with pleasure that the University of Cambridge has conferred upon Mr. Francis Galton the honorary degree of Doctor of Science. Mr. Galton is well known as the author of "The Art of Travel," and as having introduced into this country the Bertillon system of identification of criminals.

THE Croonian Lectures of the Royal College of Physicians of London will be delivered at the college, Pall Mall East, on Tuesday, June 18th, Thursday, June 20th, Tuesday, June 25th, and Thursday, June 27th, at 5 P.M. by Dr. Marquet. The subject of the lectures will be a "Contribution to the History of the Respiration of Man."

FOOTBALL FATALITY.—On the 14th inst., while playing a game at East Clandon, a young man aged twenty-one years charged another player and was shortly afterwards seized with illness and died on his way home.

REPORT OF THE COMMITTEE ON PRISONS.

III.¹

AFTER urging the development of prison industries, and pointing out how strongly the evidence testifies to the benefits derivable by prisoners from being engaged in productive labour, the committee pass on to speak of "Prison Occupation generally"; and they think that there should be a larger supply of books and that reading should not be restricted to one book a week if the prisoner cares to read more, the only difficulty standing in the way being that of distribution, which should readily be overcome. With regard to the general occupation of prisoners other than that devoted to labour, meals, chapel, and other necessary prison duties, the committee hold that everything should be encouraged which tends to elevate the mind so far as it is consistent with regulations necessary for the general order and discipline, much depending in this respect upon the kind of population in a prison and upon the individuals who compose the prison staff. "The monotony of chaplains' work in prisons is apt to produce a mechanical performance of duty, and we think that it would be advisable more often to bring in selected preachers from the outside and we suggest that where it is possible the number of services which the prisoners have to attend should be reduced. This would enable the prisoners to be divided, each half going to chapel on alternate week days." These suggestions appear to us to be wholesome ones and well calculated to relieve the humdrum character of services and make chapel-going less of the nature of a punitive routine. The committee inquired carefully into the rules which regulate "talking" in prisons. Female convicts are allowed to talk for at least an hour a day under proper supervision, and so far as the committee can learn no harm has resulted from it. "We think the privilege of talking might be given after a certain period as a reward for good conduct on certain days for a limited time, and under reasonable supervision, to all long-sentence prisoners, local as well as convict, who have conducted themselves well and who are not deemed unsuitable for the privilege. The present practice of imposing silence, except for the purposes of labour and during the visits of officials and authorised persons, for a period it may be of fifteen or twenty years, seems to us unnatural." In the matter of "Education," the committee think that better results would be obtained by establishing a practice of teaching in classes and by extending tuition to the prisoners generally who, it might be considered, would be the better for it, and not limiting it to prisoners with a sentence of over four months, as at present.

The committee rightly attach great importance to the subject of Classification. It appears that in the prison service a "juvenile" is a boy under sixteen, for whom special treatment is provided by the Prison Act, 1865. Several witnesses were in favour of the total discontinuance of committing this class of offenders to prison; but the committee do not think this is either practicable or desirable. But although they think that in the case of grave offences for which reformatories are not available imprisonment is necessary, they hold that children should be subjected to special treatment and kept absolutely apart from other prisoners. The total number of this class on March 31st, 1894, was only 100, and it might be possible to set apart one of the London prisons for the reformatory treatment of this class. With regard to "young prisoners" the committee speak as follows: "Taking prisoners generally in local prisons, on March 31st, 1894, there were 2226 prisoners, all told, between the ages of sixteen and twenty, and there were 4880 between twenty-one and twenty-nine inclusive. After thirty a very distinct decrease in the number of prisoners proportionately to the population of the same age sets in. Doubtless this decrease is due to various causes, but the fact that it occurs suggests that this tendency towards the abandonment of criminal practices may be strengthened by developing the reformatory side of prison life." The following figures are interesting as showing the proportion of persons convicted for indictable offences per 100,000 of the population of the same age: under twelve, 24; twelve to sixteen, 261; sixteen to twenty-one, 321; twenty-one to thirty, 245; thirty to forty, 204; forty to fifty, 143; fifty to sixty, 92; and above sixty,

¹ Parts I. and II. were published in THE LANCET of May 4th and 18th respectively.

56. In this relation it is to be borne in mind that there is a strong tendency towards short sentences in the case of young offenders, so that the same individuals will appear oftener in the list at the earlier ages. The committee point out that the years seventeen, eighteen, and nineteen appear to be the most fatal in the formation of lasting criminal habits, and that this fact denotes a degree of plasticity which might be made use of in the right direction. They recommend that the age of admission to reformatories should be raised from sixteen to eighteen and of detention to twenty-one, and they urge the establishment of a penal reformatory under Government management on the ground that young offenders would thereby not be compelled to come in contact with the experience of prison life, and would, moreover, receive a good education and be trained in various kinds of industrial work and brought under the best and healthiest kind of moral influence. We are strongly of opinion that such a scheme, brought to bear upon youths at what is the most impressionable period of their lives, would, if properly carried out, be a great power for good in reclaiming many whose predisposition to enter the criminal ranks is largely fostered by the nature of their ordinary surroundings; but it will be useless if it is entered upon in a half-hearted way and upon a niggardly basis, for the machinery calculated to bring about the best results must be well appointed and equal to the work both as regards material appliances and personal capacity of staff.

Proceeding to treat of "Habitual Criminals," the committee recommend that this class of prisoners should be kept as a class apart from others, and they are strongly of the opinion that further corrective measures are desirable for these persons, who are a nuisance to the community, who when at large are responsible for the commission of the greater part of undetected crime, and who, when under sentence, complicate prison management. "We venture to offer the opinion formed during this inquiry that a new form of sentence should be placed at the disposal of judges by which these offenders might be segregated for long periods of detention, during which they would not be treated with the severity of first-class hard labour or penal servitude, but would be forced to work under less onerous conditions. As loss of liberty would to them prove eventually the chief deterrent, so, by their being removed from the opportunity of doing wrong, the community would gain." Under the head of "Habitual Drunkards," the committee say, should be included most prisoners sentenced primarily for drunkenness. They are not criminals in the ordinary sense and should stand by themselves in a special category. The committee go on to say that their inquiry entirely confirms the recommendation of the departmental committee on inebriates that magistrates should have power to commit for lengthened periods habitual drunkards coming before them. "Apart from any places of detention which may be constituted by legislation consequent on the report, we think that persons committed to prison for this offence should be collected in separate prisons, if possible, or otherwise in parts of prisons reserved for them. Special medical treatment should be applied to them, and they should be dealt with as patients rather than criminals."

Special consideration is needed in the treatment of female prisoners who are admitted into prison with infants or who are confined after entering prison. The infants should be in a *criche* in charge of a warder, the mothers being admitted at fixed time and otherwise employed like other prisoners. If ill-health makes it necessary for the mother to stay with the infant they should be in a hospital cell. Their presence in the ordinary prison destroys discipline, as they will talk; they cannot be punished and in every way they are exceptional cases. The present system of locking up the woman in a cell is unnatural and has bad effects, physical and moral. Wide discretion should be allowed to the matron and medical man as to the removal of the child at nine months of age. In cases where the mother is not satisfied that the child will be cared for it should be either retained in prison or the mother should be released with it. We are glad to have an opportunity of endorsing these comments of the committee on this subject, as they are clearly founded on common sense and natural instinct. To every rule, no doubt, where women of this class are concerned it is not unlikely that some cases of exceptional difficulty may arise, but the general principles formulated by the committee are excellent.

With regard to Unconvicted Prisoners, the committee concur generally with the views expressed by the Royal Commission of 1884 on Irish Prisons, whereby greater

freedom and more substantial modification of the severe restrictions were advised, on the ground that these prisoners are confined "for safe custody only." The committee do not think the provision made by the Prison Act of 1877, and insisted upon by the Royal Commission, with the view of their confinement being regulated in such manner as to make it as little as possible oppressive, has been duly carried out; and they think the diet of unconvicted prisoners should be improved. With regard to Debtors, they hold that there seems to be no sufficient reason why they should be more favourably treated than other prisoners. The question of classification is one by which the committee lay great store in their hopes, for "the special classes will be kept together, and it will be easier to apply to them the necessary special treatment. There will be less confusion, because in the case of the young offenders in the penal reformatories the habitual criminals and drunkards, those who undergo considerable periods of detention, will be grouped together, and greater facility afforded for teaching them a skilled trade." In this we entirely agree, and for that reason we have been anxious to set forth the views of the committee at some length. If any alteration in our prison system is to be the outcome of this committee, we feel sure it will have to take the form, not of altering the method of dealing with the inmates of our prisons as at present mixed up almost indiscriminately, but of rearranging and placing upon a more systematic basis of classification the various groups of criminals in relation to the nature and the intensity of their criminality. Such a process is that which the committee appear anxious to initiate, or rather to develop. A great deal has been done in the last thirty years to place the internal management of our prisons on a footing more consistent with modern ideas as to the efficacy of reformatory principles, as compared with mere efforts at repression. The subordinate staff, we are assured, carry out their "most difficult and responsible duties with forbearance and kindness," but from the nature of the circumstances those duties are of necessity very largely of a mechanical and routine description. It is to the higher officials and to the opportunities which may legitimately be entrusted to them that we must look for what we regard as the influential and abiding effects of the educational process, which should more especially characterise the operative activity of prison life, upon the minds of criminals. In this sense a careful and well-considered classification comes to be of vital importance, and the committee have done well in drawing public attention earnestly and forcibly to the necessity for it.

THE VESTRY OF ST. GEORGE, SOUTHWARK, AND THEIR MEDICAL OFFICER OF HEALTH.

(SPECIAL REPORT TO THE VESTRY.)

WHEN I had the honour of being appointed as medical officer of health to St. George's I agreed to obey the order under the Public Health (London) Act relating to the duties of medical officers of health. At the same time I consented to carry out a certain additional duty—namely, "to attend, if required, the sewermen, flushers, and employes during sickness." This agreement I signed under the impression that the particular duty had received the sanction of the Local Government Board, and would, therefore, come under Article 18 Subsection 18 of this order.

Subsection 18 reads as follows: "In matters not specifically provided for in this order the medical officer of health shall observe and execute any instructions issued by us, and the lawful orders and directions of the sanitary authority applicable to his office."

I mention these points because of their bearing on the following circumstances. At a meeting of the vestry on March 12th, 1895, a recommendation was "received" from your works committee to the effect "that in the event of the permanent hands of the vestry being absent from work for two or more days consecutively owing to alleged illness, the surveyor shall notify the medical officer of health, who shall attend the cases in accordance with Section 19 of the terms of his appointment, and afterwards report to this committee." Shortly after

this resolution I received a bundle of medical certificates, duly signed, referring to thirteen employés who lived in various and sometimes in distant parts of London. At the same time I had a verbal request from the surveyor to attend these thirteen cases. In such a proceeding I foresaw great difficulties, such as, for instance: (1) my unfitness for the work, as I have given up active practice for many years; (2) loss of time from regular duties; (3) friction with medical men of the district who were attending the patients in question. On these and other grounds I determined, after consultation with your vestry clerk, to refer the matter to the next meeting of the vestry. This I did on March 26th, 1895. The minutes of that date record that "the medical officer of health stated he was not quite clear as to the intention of the vestry with regard to the resolution passed at the last meeting instructing him to visit the vestry employés during illness." At that meeting I pointed out the serious difficulties that would arise from my visiting the patients of another medical man without his knowledge. The matter was referred back to the works committee for further consideration.

Quoting from the minutes of the latter committee for March 28th I find it written: "The question of the medical officer of health visiting employés during illness referred from the vestry was before the committee." "After some considerable discussion on the matter it was resolved that in any case where the surveyor is of opinion any suspicion is attached to any employé he shall notify the medical officer of health, who shall accordingly visit the men, the vestry undertaking to be responsible for any irregularity thereto." This resolution did not appear in the vestry's printed agenda, but was read on April 9th from the works committee minutes. On that occasion I made a statement to the effect that I begged respectfully to decline visiting the employés, unless I informed the medical man in attendance of my proposed visit. This statement does not appear either in the vestry's printed agenda or in the minutes of the 9th of April. It was, however, read on the 25th of April by the shorthand clerk at a meeting of the works committee, to which the matter had been again referred. At that meeting I asked the chairman kindly to explain to me the exact wishes of his committee. He answered that I was expected to see employés certified as sick without previous communication with the medical man in attendance. In other words, I was to make what are known as "surprise visits." I thereupon observed that both in my own interests and also in those of the parish I could not consent to such a proposal; but that I was willing, with the consent of the medical man in attendance, to see employés suspected of malingering, and that, moreover, I should prefer to meet him in consultation. I also made inquiry of the chairman as to what extent and in what manner it would be possible for the vestry to be responsible for the unprofessional conduct they asked me to be a party to. To this question I received no answer. The committee then resolved that their resolution of March 28th, which undertook a somewhat vague responsibility on behalf of the vestry, be reaffirmed. This resolution, which did not appear on the printed agenda, was duly "received" by the vestry after the reading of the committee's minutes on May 7th. There is no record, however, of the resolution having been "adopted" by the vestry.

On May 14th I received a note from your surveyor requesting me to visit a sick employé, and enclosing a certificate dated the same day, and signed by a doubly qualified medical man. I took the earliest opportunity available of seeing the surveyor personally, and was told that the vestry clerk had reported the case to him on information received from certain members of your vestry. With the surveyor's consent I repeated these words to Mr. Millar (the vestry clerk), who told me in emphatic terms that I had been misinformed. It is now my duty to state to the vestry that the patient in question has not been seen by me for reasons similar to those that have been already given. I take the present opportunity of respectfully asking for a final settlement of a matter that has already occupied a large amount of your valuable time.

Trades unions exist in almost every calling, and the profession is not free from a similar governing principle. It is a first understanding, equal in force to law, that every medical man should refrain from interfering with a patient already under the care of a brother professional unless by his consent, or, better still, in consultation. With no class of men is the observance of unwritten laws more necessary than among medical officers of health, whose duty

brings them in constant touch with local practitioners. Any friction between the sanitary authorities and the medical profession would, I feel sure, soon work disaster in a district like St. George's. Without in the least degree wishing to escape from any obligation entered into between your vestry and myself, I would respectfully ask that a final and speedy decision of the matter referred to in this report be requested from the Local Government Board.

(Signed) F. J. WALDO, M.D.,
Medical Officer of Health.

Vestry Hall, St. George's, Southwark, May 21st, 1895.

THE PRODUCTION OF DIASTASE AND OF AN ALCOHOLIC FERMENT FROM FUNGI.

IT is a relief to turn from the study of the micro-organisms which produce disease in man and to consider the important functions of other micro-organisms which we know are instrumental for his good. The training of useful microbes with a view of utilising their latent beneficent powers is, however, a branch of practical study which has hitherto resulted in small success; but there is little doubt that before long certain microbes will rank with other organisms in ministering to the needs of mankind if only the means of directing their movements and action are discovered. The present position of knowledge upon this subject undoubtedly points to the possibility of bacteria being schooled to perform a multiplicity of operations, useful and even industrial, which at present admit of being more satisfactorily and economically carried out. The vexed question of the disposal and utilisation of sewage matters, for example, promises soon to be solved most satisfactorily by bacterial methods, for the experience gained in the remarkable experiments at Massachusetts, as well as those in our own country by Mr. Scott-Moncrieff, teach that there are forces at our disposal in the army of bacteria above, beneath, and around us which when properly engineered will accomplish not only the disposal of a nuisance, as sewage is, but convert it into substances of an innocuous character to man and of a positively beneficial character to plants. Thus under suitable conditions it has been shown that the organic nitrogen, carbon, and hydrogen of sewage is converted by certain bacteria into the simple products ammonia, nitrate, carbonic acid, and water, the very constituents upon which plants thrive and feed, and which are, we might say, their very bread and butter. Illustrations of this kind of the important and useful functions played by microbes in serving the interests of man could be multiplied; suffice it to add that in the present article it is proposed to record but one other example which has recently come to our knowledge, and in which the importance of, and the profit that may accrue from, a study of the habits and requirements of organisms are well brought out. We refer to the recent researches of a Japanese chemist, which were instituted with a view of utilising the property possessed by certain fungi during their growth upon suitable media of exciting both diastatic and fermentative action. The results ultimately obtained promise to become of great commercial importance, while they have also a distinctly interesting bearing upon medicine, not only in bringing to light the eccentricities of organisms and expanding our knowledge of the nature of fermentation, but because one at least of the products—viz., an exceedingly active diastase and probably the purest form of this interesting enzyme ever produced on the large scale—has already its distinct uses in medicine and dietetics. A consideration of these points justifies us, therefore, we think, in devoting some space to an account of this new and important discovery; and at the same time we may append the results of a few experiments we have been able to make in the laboratory with the view of satisfying ourselves in some measure—and therefore, we venture to believe, our readers—as to the validity of the statements made in regard to it.

The discovery is due to a Japanese chemist named Jokichi Takamine, who, while studying with Professor Mills, F.R.S., at Glasgow University, conceived the idea of improving the methods of brewing and distilling—that is to say, he satisfied himself that better converting and fermenting agents were obtainable, and that the tedious, costly, and not over-healthy process of malting was a clumsy and

primitive mode of obtaining a converting agent in the form of the small production of diastase developed at so much sacrifice to the grain treated. On returning to Japan, Mr. Takamine, jointly with Professor Atkinson of Tokyo University, who published occasional contributions on the subject, undertook a long and exhaustive series of studies and experiments on many kinds of microscopic fungus or mould-growth, his object being to find a class of plant containing the two qualities of converting starch in cereals into sugars, and the sugars so obtained into alcoholic spirits. The various ferments and processes of the East, as well as of Europe, were one by one investigated only to be discarded by him; the ergots of rye and other plants whose qualities and powers are well known were not neglected; many kinds of bacteria were studied, when eventually this chemist discovered what he required in the fungus of the species *Eurotium Oryzae*, a mycelial of the *Aspergillus* family whose nature and characteristics were almost unknown. The qualities required and found in this fungus were threefold—that is, the plant having the two qualities he was seeking had to possess another quality, that of being capable of withstanding a high artificial cultivation or development of the two qualities. The best and most practical medium used for growing the seed of this microscopic fungus is common hydrolised wheat bran, on the flakes of which the plant grows with great rapidity, and whilst growing it, to reproduce its own seed, is fertilised with certain chemical salts, and when matured, a process of about five days' duration, he calls it "Taka Moyashi." When grown for commercial purposes it is not fertilised, neither is it allowed to ripen in the same high-class cultivation in this form, the commercial product being known as "Taka Koji."

On examining Taka Koji with a microscope the bran flakes show, after being thirty-six to forty hours in a moist temperature of 80° F., that the roots which spread all over the surface of the bran are literally covered with minute crystals of pure diastase. At the top of the mycelial a small head is formed in which the seeds and pollen are present, while the diastase at the roots is the ferment or agent which converts starch into sugars, the unripe seeds permeated with the pollen, and which may be designated in this condition spores, since they give rise to the ferment or agent which converts the sugars into alcohol and which now takes the place of yeast, as the diastase replaces malt. Strange to say, when both characteristics of the fungus are at their best in this inferior cultivation as described, their properties are at their highest stage of commercial utility; but should the higher temperature and fertilisation be resorted to it is found that the diastase is entirely absorbed from the roots by the seed in the head of the mycelial, which it serves to nourish and ripen, and when the two agents become one, capable of reproducing their genera, it is found to be of little use for either purposes, for converting or fermenting. Mr. Takamine obtains his diastase in an almost pure and concentrated form by the use of percolators, washing the diastase from the bran with water, in which it is soluble, but not so in alcohol, in which it is precipitated. When dried it is of a pure crystalline nature, capable of preservation for any length of time.

The purified diastase product consists of small, tenacious, gummy particles of a light brown colour and somewhat of the appearance of finely broken shellac; it is almost devoid of taste, but it communicates a peculiar sensation on the tongue, indicative of active digestive properties. An analysis which we made gave the following results:—

	Per cent.
Moisture	15.46
Albuminoids (N=3.65)	22.80
Mineral matters, consisting chiefly of soluble phosphate	16.22
Non-nitrogenised matter, probably carbohydrate... ..	45.52

On trying a weighed portion with a standard starch solution it was found that over 100 times of its weight of starch was completely converted in thirty minutes at blood heat. Doubtless at higher temperatures it would convert even a much larger quantity, it being stated that under favourable conditions it will digest as much as a thousand times its weight of starch. Hitherto the digestive properties of diastase have been appropriated chiefly by using active extracts of malt, which of course contain a large excess of malt sugar, which in certain cases it is desirable to exclude. The use of the "Takamine diastase" therefore offers

obvious advantages on this head. It can be employed, for example, for the malting of milk preparatory to drying, while it can be introduced almost imperceptibly to the taste into beer and other beverages without adding objectionably to the sugary constituents. It can also be compressed into tablets and in that form be obviously useful for a variety of medical and dietetic purposes. The expense of obtaining diastase by the new process is so small that it will be cheaply available for all purposes, including that of bread-making. It is this product of the new discovery, but in a less concentrated and in a less expensive form, which is expected to take the place of malt to a great extent in breweries and distilleries, while the ferment is calculated to replace the present yeasts of commerce in consequence of its greater power, quicker action, and superior keeping qualities.

As already stated, Taka Koji possesses two distinct properties—namely, diastatic property, or property of converting starch into sugar, and fermenting property. It is exceedingly important from an economical standpoint to separate these two properties, as well from the Taka Koji as from each other—a separation that has never before been successfully accomplished on an economical scale—so that when a conversion is desired the ferment property need not be wasted, and when fermentation is desired only the ferment property of the Taka Koji may be employed without waste of the diastatic property. The ferment portion may be directly separated from the dried Taka Koji, in the form of a fine powder, by sifting the Taka Koji. This powder comprises the bloom of the fungus and possesses fermenting properties in a remarkable degree. The residue left after sifting contains the diastatic property, and may be used as a diastatic agent. These two properties may be extracted together from the Taka Koji by soaking or steeping the same in water, thoroughly stirring and then pressing the mass, the diastatic property dissolving in the water, and the ferment part, insoluble in water, becoming detached by attrition and remaining suspended in the liquid. The soaking or steeping, separating and pressing operations may be repeated as often as may be desired, in order to effect a thorough separation. The ferment may be separated from this solution by decantation or filtration. It is, in the form of a fine dry powder, composed of young, immature spores of the mycelial fungus, the colour varying with the different fungi employed. It consists of microscopical spherical cells possessing the property of being transformed into alcoholic ferment cells when submerged in sugar solution under suitable conditions. Fermentation with this "Taka Moto," as it is called, proceeds with remarkable regularity and briskness, the liquid having all the appearance of a weak acidulated solution of sodium bicarbonate, so brisk is the effervescence. On microscopical examination the deposit was seen to consist of budding cells perfectly uniform and regular in shape and like the spores of *mucor* or some allied fungus, which have pululated instead of producing a mycelium. Mr. Takamine uses the microscopic fungus *eurotium oryzae* with the best results. But other mould fungi belonging to the genus *aspergillus* and to the genera *mucor* and *penicillium* may also be employed. The Moto may be dried and used for all the purposes for which common yeast is at present used. It is claimed that the *aspergillus* yeast for bread-making will work in half the time required by yeast, and will produce sweeter and more wholesome bread. It is, besides, less liable to become sour, as the Moto itself will keep for almost any length of time in ordinary climates and temperatures. It is further stated that the Moto has the power of mastering all injurious and parasitical ferments it may encounter, and of giving off its ferment cells of a perfectly regular and pure kind.

We may next record the results of a series of experiments which we tried with the view of ascertaining to what extent the *aspergillus* yeast would work—that is, as to the quantity of spirit it is capable of producing and the amount at which its growth is arrested. It is well known that with ordinary brewer's yeast (*saccharomyces cerevisiae*), when the proportion of alcohol produced amounts to 12 per cent. the further growth of the yeast is prevented, and with 14 per cent. fermentation ceases altogether. In this respect ordinary yeast hitherto appeared to excel other organisms in resisting the action of alcohol. It is stated, however, that Taka Moto, which is a *mucor* yeast, has the power of converting a sweet solution, such as wort, containing sugar sufficient to produce 20 per cent. alcohol, while the best yeasts of commerce will not convert more than about 7 per

cent. of the sugar in a similar solution into alcohol, thus reducing, it is claimed, to one-third the volume of the "wort" to be treated to obtain the same product. How far this is so may be judged from the following series of experiments in which a mash was prepared and converted into wort by Taka Koji, and the resulting sweet liquid fermented with Moto or aspergillus yeast prepared as already described.

In the first experiment, in which a sweet liquid of a gravity of 1075 was employed, the fermentation proceeded briskly, and at the end of the experiment (seven days), the gravity being reduced to 5° under water (1000), the percentage of proof spirit on distillation proved to be 19. On feeding with more sugar, however, the proof spirit rose to 23.86 per cent. In subsequent experiments carried out on similar lines the percentage of spirit rose to 22.71 and 22.88 respectively. On pushing the process further by continuing to feed the aspergillus yeast with ordinary cane sugar a liquid was eventually obtained indicating no less than 37 per cent. proof spirit. The aspergillus yeast cells are capable of continuing their work, therefore, in a liquid containing at least and probably more than 22 per cent. proof spirit. As the spirit increases the liquid becomes clear and the copious growth of yeast at the bottom may be removed, pressed and dried, when it will be found as active as before when placed in a fresh saccharine liquid. The dried aspergillus makes an excellent yeast for bread-making, while it affords an excellent basis also for the production of alcoholic liquors from sweet solutions, especially as, unlike ordinary yeast, it is free from impurities and from those bacteria which induce undesirable changes, giving rise frequently to the formation of acid products in both the brewing of beer and the "raising" of dough in bread-making.

It is obvious from the few experiments we have been able to make that there must be a big future for the ingenious process discovered by Mr. Takamine. The simultaneous production of both a starch-converting enzyme (diastase) and of a ferment which, as we have seen, is perfectly reliable and uniform in its action is a discovery which must have a marked influence upon the brewing and spirit-producing industries. Not only is the process economical, dispensing with the loss of time which is inevitable where the converting and saccharifying powers of malt are relied upon, but it is also stated that the rectified alcohol subsequently obtained is of remarkable purity, being free, it is said, from those higher products which render the ageing and further treatment of spirit obtained in the ordinary way a necessity. Apart, however, from this interesting aspect of the new process, which has been carried out on a practical scale in America, it possesses an interest also from the purely scientific point of view, since it is illustrative, as we stated at the outset, of what can be done by paying attention to the requirements and favourable conditions under which organisms will perform a work the results of which may be eminently useful for domestic, industrial, and even medicinal purposes. In the present instance it is probable that the production of pure enzyme by the simple means above described, which will convert an extraordinary weight of starch, is a fact alone of great interest to the profession, in that it may place in their hands an agent which, as they will readily perceive, may be made instrumental for good in a variety of ways. Again, the production of pure enzyme in large quantities is calculated to afford considerable assistance to those engaged in this branch of research and in the task of unravelling the mysteries surrounding the nature and composition of these remarkably active yet unorganised bodies. When the energy of steam was for the first time utilised it was held to be a remarkable fact, but the latent energy existing in the countless microbes at our disposal must be almost beyond conception. In the remarkable process just described, for example, organisms are so as it were coaxed that they readily produce first a mighty enzyme possessing extraordinary digestive powers, and then a ferment which grows on and on, producing volumes of gas and, *inter alia*, a highly combustible body having those powerful and peculiar properties which mark the members of the alcoholic series.

THE Newbridge Dispensary Committee (Naas Union) met on the 20th inst., and elected Mr. Fleming to the post of medical officer, vacant by the death of Mr. Richard Murphy.

Public Health and Poor Law. LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria in the Hinckley Urban and Rural Districts, by Dr. S. W. Wheaton.—This report has distinct interest for those who are studying the etiology of diphtheria and allied throat diseases, but as it only records the facts collected during a second and supplemental visit to the infected localities it requires to be read together with the earlier report on the same districts issued last year and dealing with a similar prevalence during 1893. But as far as can be gathered there seems no doubt that, taking the two inquiries together, two different sets of circumstances were met with, and this either consecutively or simultaneously. Thus, in one village or set of villages there was distinct diphtheria; in another set there were groups of cases which seemed to be mere nasal catarrh, and the question arose as to how far this condition of catarrh was related to true diphtheria, and especially how far it tended to be followed by diphtheria. And the result seems to be that villages which at one time exhibited nothing but the minor malady came later to suffer severely from diphtheria—indeed, Dr. Wheaton goes so far as to refer to the prevalence of this form of catarrh as a probable indication of a prevalence of diphtheria yet to come. In the former inquiry affections of the throat and mouth were associated with the nasal catarrh, and some of these seem to have been continuous until the onset of definite diphtheria. On the other hand, the minor throat ailments met with in some places on the occasion of the first inquiry had altogether disappeared, and in such places no diphtheria was found to prevail. These affections of the throat, nose, and mouth have preceded diphtheria, they have coexisted with diphtheria during the earlier stages of that disease, and they have ceased to prevail in districts where they have been replaced by unmistakable diphtheria. The precise significance of these circumstances necessarily involves considerations of distinct interest to the epidemiologist.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 8175 births and 3569 deaths were registered during the week ending May 18th. The annual rate of mortality in these towns, which had been 17.5 and 17.7 per 1000 in the two preceding weeks, declined last week to 17.6. In London the rate was 16.5 per 1000, while it averaged 18.3 in the thirty-two provincial towns. The lowest rates in these towns were 12.3 in Croydon, 12.7 in Norwich, 13.1 in Brighton, 13.6 in Gateshead, and 13.9 in Bristol; the highest rates were 22.7 in Bolton, 23.2 in Liverpool, 25.7 in Manchester, 26.5 in Salford, and 28.7 in Preston. The 3569 deaths included 303 which were referred to the principal zymotic diseases, against 305 and 351 in the two preceding weeks; of these, 85 resulted from whooping-cough, 69 from measles, 52 from diphtheria, 50 from diarrhoea, 27 from "fever" (principally enteric), 19 from scarlet fever, and 1 from small-pox. No fatal case of any of these diseases occurred last week in Brighton, Norwich, or Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Bristol, and Bradford, and the highest rates in Salford, Bolton, Gateshead, Newcastle-upon-Tyne, and Preston. The greatest mortality from measles occurred in Bolton and Newcastle-upon-Tyne; and from whooping-cough in Leicester, Preston, Salford, and Gateshead. The mortality from scarlet fever and from "fever" showed no marked excess in any of the thirty-three large towns. The 52 deaths from diphtheria included 41 in London, 3 in Leeds, 2 in West Ham, and 2 in Birmingham. One fatal case of small-pox was registered in Liverpool, but not one in London or in any other of the thirty-three towns. There were 27 cases of small-pox under treatment in the Metropolitan Asylum Hospitals

¹ Eyre and Spottiswoode, East Harding-street, E.C.; John Menzies and Co., Edinburgh and Glasgow; Hodges, Figgis, and Co., Dublin. Price 4d.

and in the Highgate Small-pox Hospital on Saturday last, the 18th inst., against 37, 34, and 33 at the end of the three preceding weeks; 4 new cases were admitted during the week, against 12, 8, and 6 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1444, against 1469, 1413, and 1438 on the three preceding Saturdays; 185 new cases were admitted during the week, against 132, 107, and 179 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 290 and 247 in the two preceding weeks, further declined to 240 last week, and were 89 below the corrected average. The causes of 42, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Bradford, Leeds, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Salford, and Burnley.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·9 and 18·7 per 1000 in the two preceding weeks, rose again to 21·1 during the week ending May 18th, and was 3·5 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·8 in Aberdeen and 16·0 in Paisley to 22·5 in Glasgow and 23·4 in Dundee. The 608 deaths in these towns included 24 which were referred to measles, 17 to diarrhoea, 14 to whooping-cough, 5 to "fever," 4 to diphtheria, 1 to small-pox, and 1 to scarlet fever. In all, 66 deaths resulted from these principal zymotic diseases, against 71 and 59 in the two preceding weeks. These 66 deaths were equal to an annual rate of 2·3 per 1000, which exceeded by 0·8 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 26 to 30 in the three preceding weeks, declined to 24 last week, of which 7 occurred in Glasgow, 6 in Edinburgh, and 6 in Leith. The deaths referred to whooping-cough, which had been 17 in each of the two preceding weeks, fell to 14 last week, and included 11 in Glasgow. The 5 fatal cases of "fever" exceeded those recorded in any recent week, and included 3 in Edinburgh. Of the 4 fatal cases of diphtheria 2 occurred in Glasgow, 1 in Edinburgh, and 1 in Dundee. The death from small-pox was recorded in Glasgow, where the single fatal case of scarlet fever also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 124 and 98 in the two preceding weeks, rose again to 109 last week, and exceeded by 20 the number in the corresponding week of last year. The causes of 45, or more than 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 27·0 and 27·4 per 1000, further rose to 27·7 during the week ending May 18th. During the past seven weeks of the current quarter the death-rate in the city has averaged 30·2 per 1000, the rate during the same period being 17·8 in London and 19·3 in Edinburgh. The 186 deaths registered in Dublin during the week under notice showed a slight increase upon the number in the preceding week, and included 5 which were referred to the principal zymotic diseases, against 7 in each of the two preceding weeks; of these, 2 resulted from scarlet fever, 2 from "fever," 1 from whooping-cough, and not one either from small-pox, measles, diphtheria, or diarrhoea. These 5 deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rate during the same period being 1·8 in London and 3·0 in Edinburgh. The 2 fatal cases of scarlet fever were the first recorded during the present month, and exceeded the number in any week since January last. The 2 deaths referred to "fever" also exceeded the number in any recent week, while the mortality from whooping-cough showed a further decline. The 186 deaths registered in Dublin last week included 26 of infants under one year of age and 48 of persons aged upwards of sixty years; the deaths of infants showed an increase upon the number recorded in the preceding week, while those of elderly persons showed a slight decline. Eight inquest cases and 6 deaths

from violence were registered; and 71, or more than a third, of the deaths occurred in public institutions. The causes of 9, or nearly 5 per cent., of the deaths in the city last week were not certified.

HEALTH OF LONDON IN 1894.

The Registrar-General has just issued his annual summary of the mortality statistics for London and for other large English towns in 1894. The death-rate in England and Wales in 1894 was considerably lower than that recorded in any year since the enactment of civil registration in 1837; before that date no trustworthy records existed. The recorded death-rate in London in 1894 was equal to 17·8 per 1000, only 1·2 above the mean rate in England and Wales, and was lower than the London rate in any previous year for which trustworthy records exist. Corrected for difference of age and sex distribution of the population, the London death-rate last year is raised to 18·93, which may be compared with the rate in England and Wales, 16·59. Put in another way, there were in equal numbers living, with equal sex and age proportions, 1141 deaths in London last year to 1000 deaths in England and Wales—the excess of mortality in London being thus equal to 14·1 per cent., against an excess, calculated in the same manner, of 18·6 per cent. in 1893. Among the thirty-three large English towns specially dealt with in the Registrar-General's returns, ranged in the order of their rates of mortality from the lowest, London stands sixteenth in the list for 1894, whereas in 1893 it stood seventeenth. The annual summary contains an international table of mortality in large towns, in which statistics are given for six foreign cities with populations exceeding a million. The death-rates in these six towns in 1894 ranged from 18·2 per 1000 in Berlin to 22·8 in Vienna; whereas in London the recorded rate did not exceed 17·8. The death-rates in the five metropolitan groups of registration districts ranged from 16·2 in the west and north, to 20·6 and 20·9 respectively in the central and east. The summary gives no statistics of mortality at the different age periods except as regards infant mortality. The deaths of infants under the age of one year were equal to 143 per 1000 born alive, whereas the mean rate in the ten preceding years was 154 per 1000; infant mortality ranged in the groups of registration districts from 131 in the north to 158 in the east. Infant mortality, showed, however, a far wider range in the various metropolitan sanitary areas; it was only 86 per 1000 in Stoke Newington and 94 in Lee and Plumstead, while it ranged upwards to 185 in St. George-in-the-East, 186 in St. George Southwark, and 210 in St. Martin-in-the-Fields. After correction for increase of population the deaths in London last year were 11,660 below the mean annual number in the ten preceding years. If we except a marked excess from diphtheria (1146 deaths) and a smaller excess from measles, influenza, cancer, premature birth, and suicide, the mortality from all the principal causes of death in 1894 was below the corrected average. The deaths referred to diseases of the respiratory system were 5000 below the corrected average. Diphtheria was again last year one of the most fatal zymotic diseases in London, and caused a death-rate of 0·61 per 1000, which, although showing a decline from the still higher rate in 1893 (0·74), was nearly double the mean rate in the years 1885-93, which was 0·36. The deaths referred directly to influenza, which had been 2336, 2264, and 1526 in the three preceding years, further fell to 750 last year. One of the most noticeable features in the mortality statistics in the annual summary just issued is the abundant evidence it affords of the low sanitary condition of the group of registration districts representing East London. It has been seen that the death-rate from all causes in this part of the metropolis showed a marked excess. The recorded death-rate in East London, however, probably understates the true corrected mortality, as the birth-rate in this group of districts in 1894 was 36·4, while the highest rate in any of the other groups was 30·7 in South London. The death-rate from the principal zymotic diseases was 3·52 per 1000 in East London, whereas the highest rate from these diseases in the other groups was 2·64 in the South. Diphtheria and measles especially showed a marked excess in East London; and we have already called attention to the excess of infant mortality in this part of London. While there is the most conclusive evidence of continued general health progress in London, the statistics for the eastern and for some of the central districts point clearly to the necessity for more earnest and active sanitary action in those localities.

THE SERVICES.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel Daniel C. Grose to be Surgeon-Colonel, vice F. H. Welch, retired. The under-mentioned Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels:—William J. Fawcett, M.B., vice G. Andrew, M.B., retired; William E. Saunders, vice D. C. Grose; William J. Charlton, vice J. D. Gunning, deceased.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen's approval of the following promotions among the following officers of the Indian Medical Services appears in the *London Gazette*, May 17th:—*Bengal Medical Establishment*: To be Surgeon-Major-General: Surgeon-Colonel James Cleghorn, M.D. To be Surgeon-Colonels: Brigade Surgeon-Lieutenant-Colonel John Henry Newman, M.D.; Brigade-Surgeon-Lieutenant-Colonel James Charles Gordon Carmichael, M.D. Her Majesty's approval of the retirement from the service of the undermentioned officers is also gazetted:—*Bengal Medical Establishment*: Surgeon-Major-General William Roche Rice, M.D., C.S.I.; Brigade Surgeon-Lieutenant-Colonel Archibald Cameron, M.D. *Madras Medical Establishment*: Brigade-Surgeon-Lieutenant-Colonel James Smith; Surgeon-Major Donald Elcum, M.D. The following appointments are announced:—Hyderabad Contingent: 2nd Infantry: Surgeon-Captain C. A. Johnston, Madras Establishment, officiating Medical Officer, 1st Lancers, to be Medical Officer. Surgeon-Major P. D. Pank (Bengal), Residency Surgeon in Meywar, to officiate as Civil Surgeon of Ajmere and to the Medical Officer of the Merwara Battalion until further orders. Surgeon-Major H. N. V. Harington (Madras), Medical Officer of the Deoli Irregular Force and of the Haraoti and Tonk Poll Agency, to officiate as Residency Surgeon in Meywar until further orders. Brigade-Surgeon-Lieutenant-Colonel C. F. Pollock, A.M.S., to officiate on the Administrative Medical Staff of the Army, with the temporary rank of Surgeon-Colonel. Brigade-Surgeon-Lieutenant-Colonel R. de la C. Corbett, D.S.O., A.M.S., to officiate on the Administrative Medical Staff of the Army, with the temporary rank of Surgeon-Colonel. Brigade-Surgeon-Lieutenant-Colonel H. T. Brown, A.M.S., to officiate on the Administrative Medical Staff of the Army. Surgeon-Major A. V. Anderson and Surgeon-Major A. W. F. Street, D.S.O., have respectively delivered over and received charge of the office of the Deputy Sanitary Commissioner, Central Registration District. The services of Surgeon-Major J. T. Lewtas, M.D. (Bengal), Officiating Statistical Officer to the Government of India, are replaced at the disposal of the Government of Bengal. The services of Surgeon-Captain G. H. Fink, Civil Surgeon, are placed at the disposal of the Government of India, Home Department. Surgeon-Captain J. C. Morgan, A.M.S., takes over the duties of Staff-Surgeon at Murree from Brigade-Surgeon-Lieutenant-Colonel G. Massey, Civil Surgeon.

NAVAL MEDICAL SERVICES.

The following appointments are announced:—Staff-Surgeons: Samuel Keays to the *Tamar*; James McCardle Martin to the *Colossus*; and Horace Ximenes Browne to the *Melampus*. Surgeons: Edward R. D. Fasken to Sheerness Dockyard; James C. F. Whicher to the *Wye*; Hamilton E. L. Carle to the *Victory*; Percy Lord to the *Tamar*; Percival M. May to the *Esik*; R. J. Mackeown, A. R. Bankart, P. H. M. Star, E. S. Miller, H. H. Pearse, O. Rees, H. A. Julius, C. H. Rock, S. T. Reid, F. W. MacVean, J. F. Hall, H. W. Hull, C. J. E. Cock, J. E. H. Phillips, T. Gibbons, and A. X. Lavertine to the *Victory*, for Haslar Hospital.

VOLUNTEER CORPS.

Artillery: 1st Norfolk (Eastern Division, Royal Artillery): Harold Muir Evans, M.D., to be Surgeon-Lieutenant. *Rifle*: 2nd Volunteer Battalion, the Royal Warwickshire Regiment: Surgeon-Lieutenant W. G. Creswell, M.D., to be Surgeon-Captain. 5th (the Hay Tor) Volunteer Battalion the Devonshire Regiment: Lieutenant John Quick to be appointed Surgeon-Lieutenant. 1st Volunteer Battalion the Lancashire Fusiliers: Surgeon-Captain A. Fletcher, M.D., resigns his commission. 1st Volunteer Battalion, the East Lancashire Regiment: Surgeon-Lieutenant J. M. H. Martin, M.D., to be Surgeon-Captain. 2nd Volunteer Battalion, the East Lancashire Regiment: Surgeon-Lieutenant A. M. Sinclair to be appointed Second Lieutenant. 1st Surrey (South

London): Surgeon-Captain T. A. Dagg resigns his commission. 21st Middlesex (the Finsbury): Evan Jones, gent., to be Surgeon-Lieutenant. *Volunteer Infantry Brigades*: North Midland Brigade: Brigade-Surgeon-Lieutenant-Colonel W. Milligan resigns his appointment.

DEATHS IN THE SERVICES.

Deputy-Surgeon-General John Ashton Bostock, C.B. (retired), whose remains were interred at Brookwood on Tuesday last, and who had reached the ripe age of eighty years, was educated at the Charterhouse and at Cambridge. In 1838 he passed his examination for the Membership of the Royal College of Surgeons of England, and four years later was appointed assistant surgeon in the Army, reaching the rank of surgeon-major in 1857; he retired in 1876. He took part in the first Afghan War, which closed in 1842, and was also engaged in the Crimean War. For these latter services he received the medal with four clasps (Alma, Balaklava, Inkerman, and Sebastopol) and the Turkish medal. He was also made a Knight of the Legion of Honour. After his retirement in 1876 he took a special interest in the work of the Metropolitan Asylums Board and actively associated himself with many questions concerning the public weal. Among those who attended the first part of the funeral service, which was held in the Guards Chapel, Wellington Barracks, were Surgeon-Captain Bostock, Surgeon-General Gordon, Dr. Farquharson, M.P., Dr. Bridges, Surgeon-Major Duke, Professor Rucker, F.R.S., Dr. Rogers, Dr. Hare, Brigade-Surgeon Perry, Professor William Smith, Dr. Kingston Barton, Dr. D. Slater, Dr. Church, Sir Edwin Galworthy, Sir James Paget, and Mr. J. T. W. Macalister (Librarian of the Royal Medical and Chirurgical Society).

Deputy Inspector-General E. Moorhead, M.D., Retired List, Army Medical Department, died at Margate, on the 6th inst., aged seventy-five years. He joined the Army in 1842, became surgeon in 1855, surgeon-major in 1862, and retired with the hon. rank of deputy-surgeon-general in 1868. He served with the 32nd Regiment at the first and second siege operations before Mooltan, including the capture of the city and surrender of the fortress (medal with clasp).

Deputy-Surgeon-General H. Harper, Madras Medical Service (retired), died on the 3rd inst.

Brigade-Surgeon-Lieutenant-Colonel J. D. Gunnings' death at sea on the homeward passage of the *Malabar* is announced. He joined the Army in 1867, became surgeon in 1873, surgeon-major in 1879, surgeon-lieutenant-colonel in 1887, and brigade-surgeon-lieutenant-colonel in 1893.

THE HEALTH OF CALCUTTA AND BOMBAY.

We referred last week, in a paragraph under this heading, to the alleged prevalence of typhoid fever in addition to that of small-pox and cholera, which had been previously reported. It appears, according to the *Times of India* of the 4th inst., that a severe outbreak of typhoid fever has also recently occurred at the Sailors' Home in Bombay amongst the crew of H.M.S. *Cossack* whilst they were being temporarily quartered there in consequence of their ship undergoing repairs in the dry dock. The first case reported was on Feb. 19th, and between then and the 24th there were 11 cases. These were followed by other cases on the 28th of the same month, when the total number reached 22, exclusive of 8 cases of a doubtful or less pronounced character. The deaths numbered 8. From an inquiry that has been instituted and is still being prosecuted it would appear that no sufficient cause has been discovered in the building itself or in its sanitary appliances to account for the outbreak. The result of the investigation, so far as it has gone at present, is stated by our Indian contemporary to have established a strong probability in favour of the theory that milk pollution and the use of polluted watercress have been the causes of the disease in question. We hope that the condition of any filters that may have been in use in the institution will not escape attention. The water-supply is obtained from the municipal mains, and the water at its source is believed to be perfectly good.

TEMPERANCE IN THE ARMY.

The Duke of Connaught, who presided over the first public meeting of the Army Temperance Association, held last week at the Royal United Service Institution, in appealing for funds, made some interesting remarks with regard to temperance amongst the rank and file of our army. Of its immense moral power for good he said there could be no doubt, and when men left the army and returned to civil life, if they had good characters, they stood a better chance of

getting employment. To belong to the Army Temperance Association was a testimonial as to sobriety, and His Royal Highness expressed the opinion that a soldier who was temperate was a better man than a temperate civilian, because a man who had been in the ranks was accustomed to discipline and self-control, whereas civilians were not always in the habit of checking their desires. He agreed with the suggestion that there should be a temperance room in every barracks, and that various handicrafts that would be of use to the men when they left the service might be learnt there in the men's spare time. The report showed there were 128 branches of the association, with a total membership of 8641. Lord Roberts, in a letter, expressed the hope that the present membership would be increased to at least one-third of the total number of soldiers serving with the colours in the United Kingdom, which was about the proportion of men who belonged to the association in India.

THE FRENCH IN MADAGASCAR.

According to the latest mails from Madagascar the troops of the French Expeditionary Force are reported to be suffering to a serious extent from fever and climatic disease, and the sickness has been attended with much mortality. The amount of inefficiency attributable to these causes at this season among the troops on the coast has given rise to some anxiety. It is stated that in one case a company of 150 men is only able to muster 40 fit for service; but, as those acquainted with the effects of malarial disease at certain seasons among our own troops in India are aware, the sickness and inefficiency may be excessive for a comparatively short time only. Unfortunately, however, climatic disease is apt to be followed by a good deal of debility and anemia and by recurrences of febrile attacks entailing a heavy invaliding list later.

CHOLERA AND THE INDIAN PILGRIM TRADE.

The more the facts are known the more certain it seems to be that the insanitary state of Camaran and the extremely defective state of the arrangements there make it a breeding ground for cholera. Camaran is the quarantine station through which crowds of pilgrims from India and the Dutch colonies have to pass. Large numbers of them arrive there with a perfectly healthy record as far as the voyage is concerned. They are landed at Camaran to pass the customary period of quarantine, and the usual history that follows their arrival is that some cholera cases appear among them within a week afterwards, and the disease becomes epidemic in another week. We concur with the *Times of India* in thinking it a scandal that perfectly healthy pilgrims should apparently so frequently acquire the disease at this quarantine station.

THE NAVAL EXAMINATION.

The undermentioned gentlemen who competed on the 6th inst. and following days at Examination Hall, Victoria Embankment, for appointment as Surgeon in the Royal Navy have been granted commissions:—

THE DEATH-RATE IN BOMBAY LUNATIC ASYLUMS.

According to Surgeon-General Turnbull's report on the lunatic asylums of the Bombay Presidency for 1894, the death-rate in these institutions is very high, especially in some of them. In the asylum at Poona it reached the enormous amount of 217.7 per 1000, and in another asylum at Hyderabad it was 125 per 1000. The amount of lunacy in the Bombay Presidency appears to be on the increase.

YELLOW FEVER AT ST. LUCIA.

An outbreak of yellow fever is reported to have occurred recently at St. Lucia. The disease is stated to have attacked twenty-three men of the Royal Artillery, including three non-commissioned officers, and to have caused many deaths.

Sir Alexander Mackenzie and Surgeon-Major-General Clegborn have joined the Central Committee of the Dufferin Fund in place of Sir Antony MacDonnell and Surgeon-General Rice, resigned.

The hired transport s.s. *Tabor* arrived at Portsmouth on the 10th inst. with sixty invalids for the Victoria Hospital, Netley.

Correspondence.

"Audi alteram partem."

THE CASE OF DR. CORNELIUS HERZ.

To the Editors of THE LANCET.

SIRS,—I think you may be glad to publish the enclosed certificates regarding the present condition of Dr. Cornelius Herz. The originals were forwarded for presentation to the Cour d'Appel in Paris yesterday, when the appeal came up against the recent condemnation, by default, of the accused, who has been an extradition prisoner here since Jan. 19th, 1893, without the possibility of having his case investigated, and precluded by law from giving evidence. The cruel hardship of the situation is self-evident. The unwarrantable assertions cast upon the medical testimony by the Official Advocate in the Paris court has been noticed in the *Times*, while the indecency and falseness of the comments in the lay press of France are as disgraceful as incredible. Authenticated copies of the enclosed certificates were sent to the Home Secretary here, with the covering letter of which copy is enclosed.

I am, Sirs, yours faithfully,

Saville-row, W., May 16th, 1895. MALCOLM M. MCHARDY.

[COPY.] "5, Saville-row, W., London.

"We, the undersigned, who have previously seen Dr. Cornelius Herz in consultation, have carefully read the report by Drs. Lauder Brunton and Frazer of his condition on April 27th. The increased degeneration of the heart and aorta and the increase of anginal pain is precisely what we should expect from the condition of the patient when we saw him, and from a comparison of the reports made on previous occasions with what we ourselves found. We strongly deprecate any excitement as being most prejudicial to the patient, and consider that it is advisable to spare him even the excitement and fatigue of another examination of his condition by ourselves. It is impossible for him to even leave his bed, much less to travel.

(Signed) "RICHARD QUAIN, M.D.
"WILL. BROADBENT, M.D.
"GEORGE JOHNSON, M.D.
"MALCOLM M. MCHARDY, F.R.C.S."

[COPY.] "Tankerville, Bournemouth.

"We, in consultation, saw Dr. Cornelius Herz at above address on Saturday, April 27th, 1895. He appeared even weaker than on former occasions, because whereas he had previously raised his head from the pillow to greet us he now lay perfectly quiet without even doing this. He had, however, recovered from the condition of collapse in which he had been some time before. The surface of both legs was cold, but that of the left was the colder of the two. His pulse was 86; respiration 23. The cardiac disease appeared to us to have made some progress since our last examination. The heart was feeble, so that the apex beat could not be felt, but from auscultation it was evident that the heart was dilated. The murmur at the apex indicating mitral regurgitation was louder than it had been on former occasions, and had assumed a twanging character. There was a loud systolic murmur over the aorta and a prolonged diastolic murmur over the sternum, indicating both stenosis of the aorta and incompetence of the aortic valves. How much the circulation is disturbed from this incompetence of the aortic valves is evidenced by the fact that not only was the radial artery seen to be strongly locomotive between the forefinger and thumb, but locomotive pulsation was seen even in the dorsal artery of the foot. There appeared to be also a slight thrill over the aorta which we had not noticed before and which led us to fear that the aorta itself was beginning to dilate. The pain over the heart is now nearly constant and undergoes exacerbations from time to time. The sickness continues also to be very distressing. A specimen of his urine had a specific gravity 1026, acid, slight trace of albumen and 3 per cent. of sugar.

(Signed) "T. LAUDER BRUNTON, M.D.
"W. FRAZER, M.D."

[COPY.] "May 14th, 1895.

"SIR,—I have the honour to respectfully, but most earnestly, recall your attention to my letter of Sept. 24th, 1893, regarding the exceedingly painful and cruel circumstances incidental to the prolonged custody of that mortally sick extradition prisoner Dr. Cornelius Herz, for whom it would now seem only too plain that it is deliberately intended to offer no relief otherwise than by death (mental or physical). Rather than accept any responsibility for the blood-guiltiness incidental to inaction in the matter, I herewith enclose to you authenticated copies of the medical certificates recently furnished by Dr. T. Lauder Brunton, Dr. Wm. Frazer, Sir Richard Quain, Sir W. Broadbent, and Sir George Johnson, for use in the Cour d'Appel to-morrow in Paris. There is nothing that I can add to my letter of Sept. 20th, 1893, in pleading the cause of humanity and justice as against policy routine and procrastination. I shall be glad to know authoritatively whether on the death of Dr. Cornelius Herz his family's cup of bitterness is to be further overfilled by an official inquest, as it appears too evident he is to be left to die in custody.

"I have the honour to be, Sir, your obedient servant.
(Signed) "MALCOLM M. MCHARDY, F.R.C.S.
"The Right Honourable the Home Secretary."

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—This Bill having passed its second reading in the House of Lords, it appears to me, from a perusal of the debate reported in the daily papers, that a question of some importance has been overlooked, and one which, in my humble opinion, has not received its adequate consideration. I trust, therefore, you will allow me to submit to obstetric authorities the point in question in order that it may not escape the attention of the Commons. The question is simply this. How does it come to pass—that is, if the evidence submitted to the Select Committee of the House of Commons and confirmed by that body be correct (*viz.*, that unskilled midwives have been guilty of so much mischief in the past)—I ask how it comes to pass that on the Continent, as in Germany, where the Legislature controls midwives, the mortality amongst lying-in women should exceed our own country, where legislation has not hitherto existed? Mr. Humphreys has attempted a solution of this question by informing us that the conditions of midwifery on the Continent are not the same as in the British Isles, and Mr. Humphreys further points out that narrow pelvises exist in Germany in the proportion of about 14 per cent. Now, Sirs, although personally I am no lawyer, I submit that a solemn inquiry of this kind (I mean the legislation of midwives), which for aught we know may some day shatter the whole system of obstetric practice in this country, should be subjected to the most rigid cross-examination, and it is upon this ground that I venture to offer a hypothesis to explain, at least to some extent, the curious fact of the high mortality where registered midwives exist. Now, it is perfectly evident that if the statement about these contracted pelvises be correct one of two things must take place—that is to say, violent operative measures, as craniotomy, would be more or less frequently resorted to, or the application of forceps must be a common necessity, and it is certain that in both these cases midwives would give nature the longest possible trial; and hence, the vital powers becoming exhausted, this delay may possibly account to a great degree for the high mortality in Germany, and this is exactly one of the risks—*i.e.*, delay—which we anticipate in the registration of midwives—I am, Sirs, yours truly,

Queen's-road, S.E., May 20th, 1895.

CLEMENT H. SERS.

To the Editors of THE LANCET.

SIRS,—I have obtained the following opinion on the Midwives Bill from a barrister who helped me on a former occasion. It shows the grave danger now threatening pregnant women and infants; while it will be seen that it threatens to repeal the educational sections of the Medical Acts. I can only repeat that if each practitioner will at once write to the Members of Parliament for his division, earnestly requesting them to oppose the Bill (if it come into the House of Commons), and for their Members to ask some Members of the House of Lords to oppose the Bill, it is not likely it will be permitted to pass. Each practitioner should also ask all the local influential political workers, such as the chairman and secretaries of the local political organisations, to write at once to their Members of Parliament. The Bill was read a second time by the Lords on May 14th, 1895. If some of the practitioners in each city would arrange to go as a deputation to meet their Members at the House of Commons, this would greatly assist our objections to the Bill. A list of Members of the House of Commons will be found at pages 135-147 of *Whitaker's Almanack* and the address—"House of Commons, Westminster, London"—will find them. I shall be glad to hear from any practitioner willing to help.

I am, Sirs, yours faithfully,

ROBERT R. RENTOUL.

78, Hartington-road, Liverpool, May 21st, 1895.

CASE FOR COUNSEL'S OPINION.

1. It is submitted that this Midwives Bill is, in some respects, a more dangerous proposal than either of the previous Bills. The title of the Bill is most misleading.

2. It recommends the repeal of the educational sections of the Medical Acts, as it proposes to empower a "midwife" to practise midwifery and to take entire control of the mother and infant, although she has received only a few months' training; while, according to the Medical Acts, if any person wish lawfully to practise midwifery such person must have studied for at least five years at a recognised medical school, passed the necessary medical examinations, and be registered in the Medical Register. It further recommends the repeal of the Medical Acts by enacting that a "midwife" may practise midwifery without

having studied either medicine or surgery: whereas, according to the Medical Acts, if a person wish lawfully to practise any branch or part of medicine, such as midwifery, such person must have studied medicine and surgery as well as midwifery for at least five years and passed the necessary medical examinations. It therefore proposes to revert to the effete and dangerous system of the partially educated and singly qualified practitioner.

3. It will, if adopted, prove dangerous to medical education and to the public, as it proposes to establish two separate and distinct orders of women midwifery practitioners—*viz.*, first, those trained, under this Bill, for a few months only; and second, those educated for at least five years, according to the Medical Acts.

4. It will, if adopted, prove dangerous to medical education, and to the public, as it proposes to establish a back-door entrance to the practice of midwifery; because those who fail to pass the examinations now held by the medical bodies under the Medical Acts will be able to pass the examinations held by the Midwives Board under the Midwives Bill.

5.—It will, if adopted, prove dangerous to medical education and to the public, because there is not a sufficient number of maternity hospital patients with which to train both medical students and pupil midwives in practical midwifery; and also, it would, by proposing to hand over all "normal" labours to the midwife, withdraw these from the newly qualified medical practitioner, and so prevent him from perfecting his knowledge in practical midwifery.

6.—The Bill is very one-sided, because it proposes to exclude men from the Register of Midwives, whereas women are, by the Medical Act, allowed to register on the Medical Register.

7.—The Bill is in no way whatever a protection to pregnant women and infants, because it proposes to allow every woman to continue to act as, and perform all the duties of, a midwife, so long as she does not only use the word "midwife."

8. The Bill is a threatened danger because it does not propose to make it an offence if a registered midwife employs one or several women who are not midwives to act as her unqualified assistants.

9. The Bill is a threatened danger because it does not make it an offence if a registered midwife continue to act as a midwife, even should her name be removed from the Midwives Register for infamous conduct.

10. The Bill is a threatened danger as it proposes to admit at once, and without any examination, all women who say they now act as midwives (some 15,000, the promoters of the Bill say), while it is proposed to continue this "system" of registration, without education or examination, for two years after the Bill passes (see Clause 5).

11. If the Bill became law the midwife could be employed as the legally qualified midwifery assistant of any medical practitioner, dentist, or chemist. It is difficult to see how this would protect the public.

12. The Bill does not make any provision for the supervision of midwives, even when attending natural labours, or any penalty should she neglect to call in medical assistance in abnormal labours.

13. No provision is made for the payment of the medical officers of health who "may" (not "shall") be appointed to supervise midwives (see Clause 12).

14. No provision is made in the Bill for the judging of any midwife accused of being guilty of infamous conduct and for removing her name from the Register.

15. The Bill prevents "any private person" from instituting legal proceedings against a midwife, although by the Medical Act, the Dentists Act, and the Pharmacy Act "any private person" is empowered to enter an action; while by the Veterinary Surgeons Act and its Charter "any private person" with the consent of the Registration Committee of their Council may institute proceedings.

16. The Bill neglects to give a definition to the words "natural labour," as used in Clause 2, and so would give rise to endless trouble and litigation.

17. The Bill does not define the words "without the direct supervision of a medical practitioner." Further, do the words in Clause 2 mean "registered medical practitioners only," or any unqualified practitioner?

18. The Bill does not make it an offence if the midwife conduct not only "natural" but also abnormal labours, abortions, and miscarriages. It further does not make it an offence if the midwife use instruments, or turns or performs any of the various obstetric operations. She will, therefore, be in all respects a midwifery practitioner. She will also be entitled to use the words "midwifery practitioner," accoucheur, &c. She can also ask for and accept fees for the performance of any midwifery operation (see Clause 4, line 10).

19. The Bill does not make it an offence if a midwife visits and supplies medicines to any sick, pregnant, or puerperal woman, or any woman who has aborted or miscarried, or who treats or performs any operation upon any infant. The midwife will therefore be not only a midwifery but also, if not *de jure*, *de facto*, a medical and surgical practitioner, and will be able to ask for and accept fees for so doing.

20. The Bill does not make it illegal for a midwife to vaccinate, and to take fees for so doing; or to include such in the confinement fee.

21. The Bill does not make it illegal if the midwife give a certificate of the cause of death of the mother or infant, or a certificate of stillbirth.

22. If the Bill pass a midwife will be entitled to give expert evidence in court of law as an accoucheur or midwifery practitioner.

23. The Bill does not make it an offence if the midwife compound, or supply, or dispense medicines or even "scheduled" poisons to women and infants.

24. The Bill is not fair to midwives certified and residing in Scotland and Ireland, as all such practising midwifery and using the title midwife in England may be fined £5 (see Clauses 3 (1) and 18).

25. The Bill is unfair, as it does not make any provision for the Royal Colleges of Physicians and Surgeons in Scotland, and Ireland, or for the Faculty of Physicians and Surgeons, Glasgow, or the Apothecaries' Society, Dublin, being enabled to elect each three representatives to the Midwives Board, while these medical representatives are given to the Midwives Institute.

26. The Bill fails to make provision for the election, by registered midwives, of district representatives to the Midwives Board.

27. The Bill fails to provide any penalty should any person or persons—other than those recognised by the Midwives Board—lecture, examine, and grant a certificate to women which will qualify them to act as midwives.

28. If the Bill become law a registered midwife will possess a "medical diploma," as defined by Section 27 of the Medical Act, 1886.

29. According to the definition of the term "medical corporation" in Section 27 of the Medical Act, 1886, the Midwives Board may claim to be recognised as a "medical corporation."

30. This being so, and as it is not provided against in this Bill, it follows that any medical corporation mentioned in the Medical Acts, and now granting certificates in medicine and surgery, would be entitled, by Section 3 of the Medical Act, 1886, to combine with the Midwives Board, and to recognise the Board's certificate in midwifery as one which empowered the holder to practise midwifery. Therefore the Board's certificate could, along with the medical and surgical certificates, be registered in the Medical Register.

31. To meet the necessities of the case, Clause 2 should be amended so as to define a midwife as "a woman who undertakes to act as a midwifery nurse only, and under the direct supervision of a registered medical practitioner." Clause 4 should be amended in the same way, and penalties should be provided for the punishment of any midwifery nurse who exceeds these duties.

*. We print Dr. Rentoul's letter and communication exactly as we received them, but it appears to us that a "case for counsel's opinion" is not the same thing as "counsel's opinion." We have already expressed our views with regard to this Bill, but, in accordance with the principle "audi alteram partem," we willingly insert Dr. Rentoul's letter and accompanying "case" or "opinion."—ED. L.

To the Editors of THE LANCET.

SIRS,—In your leading article of May 18th you described "the evils of the existing system, under which any woman, however dirty, intemperate, or ignorant, may call herself a midwife, without check on her practice and without responsibility to any authority"; and you further add, "It is indispensable that such persons should be ejected from the lying-in rooms of the poor," and you advocate the present Bill on these grounds. Allow me to point out that this Bill does not forbid any woman, however ignorant, practising midwifery, providing that she does not call herself a "midwife" or assume any title implying that she is registered under the Act or is "specially qualified" to act as a midwife, therefore any uneducated woman may call herself an obstetric nurse or accoucheuse and practise midwifery without infringing this Act. This is a serious matter, as this Bill is advocated on the ground that the new order of registered midwives will displace the old ignorant midwife, but it now seems that the old midwife will be retained under a new name, and there will be, in addition, a new order of registered midwives.

The result is easily foreseen; the care of the very poor will be left to the old order of midwife with her low fees, whilst the artisan's wife will fall to the lot of the new registered midwife with her higher fees. She will, therefore, come more directly into opposition with the qualified medical man, and attend many who would otherwise have been attended by him, whilst the old order of midwives will still be doing their work. How much better off will the poor be? I am, Sirs, yours truly,

May 22nd, 1895.

REGINALD PRATT, M.D.

THE RATIO BETWEEN FORCEPS DELIVERY AND RUPTURED PERINEUM.

To the Editors of THE LANCET.

SIRS,—In an interesting address by Dr. Glover, the Medical Profession, its Place and Progress,¹ after mentioning the early use of the forceps as one of the great achievements of recent midwifery practice, he (Dr. Glover) goes on to say: "True, we have heard much more of late years of accidents to the perineum." The question thus arises, "Is the more frequent use of the forceps responsible (in any way) for these cases of ruptured perineum?" It would be interesting to have the individual and collective wisdom of the profession on such a very important question. From my own midwifery statistics, extending now over more than a quarter of a century, I unhesitatingly say that, instead of the early and more frequent use of the forceps being responsible for a larger percentage of ruptured perineae, the very opposite fact is the case. I aver, moreover, that the scientific use of the forceps in applicable cases (whether early or late) is in many instances a preventive of such accidents to the perineum. On referring to my note-book I scarcely find a case of ruptured perineum occurring after the use of

the forceps, even when forcible delivery has had to be effected, whereas instances are much more numerous where delivery has been naturally accomplished. In fact, when one has the forceps on the head, one is "master of the situation," and very often by careful dallying and manipulation one can prevent such an untoward result. It must be remembered, too (which I do not recollect to have seen noted in any text-book on midwifery), that when a perineum is ruptured it is not so often from the passage of the head but from the shoulders.—I am, Sirs, yours faithfully,

Leicester, May 16th, 1895.

W. L'HEUREUX BLENKARNE.

CIVIL RIGHTS DEFENCE COMMITTEE.

To the Editors of THE LANCET.

SIRS,—On behalf of my committee I beg to express an earnest hope that you will in your widely read journal give insertion to Mr. Anderson's letter.

I am, Sirs, your obedient servant,

5, Mitre-Court, Temple, E.C., May 22nd, 1895.

STAMFORD.

TO THE RIGHT HON. THE PRESIDENT AND MEMBERS OF THE CIVIL RIGHTS DEFENCE COMMITTEE.

MY LORD AND GENTLEMEN,—The leading article in the *National Observer* of May 11th, and editorial comments in that of May 18th, coming with so much authority, coming from a friend, and with every expression of sympathy, seems so likely to carry weight and even to cause doubt amongst those who have so staunchly and so generously supported me, that I ask permission to reply, and would request that with your approval my reply be published. The *National Observer* considers the question of the original judgments of the Trinidad Court "trumpery," and, by inference, appeal to the Privy Council unnecessary; that in *Anderson v. Gorrie* and others, the judgment more than counterbalances the verdict; that the dicta I rely upon are merely "obiter"; that the judgment of the Appeal Court that no action will lie against judges for acts wholly without jurisdiction, or for striking us in the face, is correct; that there is no chance of success in appeal to the House of Lords; that the committee are in error in assisting me in either appeal, and that the proper course is that for my false imprisonment I should be compensated by the State as a measurement of "fairness"—i.e., not as of right.

The "original judgments" involved not only the money value, but (1) my right to earn my living by my profession; (2) my right to recover and enjoy possession of my freehold land, the judgments effectually impugning my title to my whole estate (against these I desire to appeal to the Privy Council, but also against each of the following illegal orders); (3) admitting and inciting the plaintiffs, who were not not paupers, to sue me as paupers, and thus depriving me of my right to my peace; (4) refusing me my right to give evidence, deserting me in effect worse than a convicted perjurer; (5) compelling me to accept twenty-four hours' notice of trial and thus preventing me from applying for a jury; (6) arbitrary refusal of my right to appeal to the Privy Council in matters involving Civil Rights of far greater value than £500; (7) for examining me in Trinidad on a Tobago judgement; (8) committing me to prison in default of bail; (9) exacting "excessive bail" contrary to the Bill of Rights; (10) refusing me the writ of *habeas corpus*; (11) refusing to accept bail when tendered, and keeping me in prison as though under a conviction for some offence; (12) repeated adjournments, without cause, keeping me a prisoner at large under "excessive bail" for three months. Is there, I would ask the *National Observer*, one of these orders that does not trespass against a right without which liberty or property would be insecure? Is there one not replete with indignity or with danger, as well as with injury? Is there one for which thousands have not suffered? I, at least, have good reason not to think them trumpery. If I had been illegally ordered to be flogged or tortured, and had been flogged or tortured, could it, I would ask, be felt that any reparation would be complete, or ought to be a satisfaction to me, without the obliteration of the shameful order? I am sure all who sympathise with me will understand me when I say that I still hear the key turn in the lock, as I heard it when I entered each night my felon's cell and the key was turned on me; and that I can never be satisfied without the formal and legal obliteration of such a record, and of others not less infamous. I trust this is no false sentiment or improper feeling, but that to generous minds the injuries thus drily enumerated may seem as intolerable to a British subject from British judges as any mere physical torture.

Yet, in the hope to appeal successfully to more practical minds, the minds of any who would advise me to disregard such wrongs and such indignities, and to accept a money gratuity and an apology in lieu of the reestablishment of my rights, and the rights of all British subjects in colonies governed by the Crown, I would ask to be permitted to point out (1) that these judgments (and orders) remain not only on record, but in force; (2) that if I give up my resistance the illegally maintained plaintiffs may not only at once enforce their illegal judgments, but thereby force on prior creditors, and make me bankrupt—sacrificing, at forced disposal, all that I of right possess, completing my "destruction" (vide *Coke*, Inst. ii., 48), and adding a final humiliation, against which for six years I have successfully struggled. I do not think the *National Observer* was aware of the position, or it would not have thought the question of the judgments trumpery. If I accept a money indemnity, am I to pay out of it these illegal judgments, and thus to give my sanction to all that I have suffered? Or are the plaintiffs to be concurrently indemnified? Or are their judgments to be annulled by Act of Parliament concurrently with the vote of indemnity to me? Even this ought not to be done except on a reference to the Privy Council and a judicial decision that the judgments and orders are illegal. Is the compensation to include all the consequential damage done to me by these "State-aided" illegalities?

For myself, I desire only my right, which is to appeal to the Privy

¹ THE LANCET, April 20th, 1895.

Council and obtain the reversal of these judgments and orders—a part of the oppression of a British colony by British judges,—which ruined many as innocent as I; which corrupted, by encouragement in speculative litigation, whole sections of the people; which criminated great numbers in conspiracy, perjury, and fraud. Between me and this oppression—between a whole colony and this wholesale judicial tyranny and corruption—there intervened, as shown by the Committee in its Interim Report, and by "Juror" in the *Pall Mall Gazette*, nothing but my right of access to a Middlesex jury. Was that, I seek to know, a "right" I did and do possess, or was it a providential error of Cave and Charles JJ.? It is now admitted that the point is far from "elementary," but this decision (without hesitation) of the Divisional Court is overlooked, and it is said that the dicta I rely upon are "obiter." It is also overlooked that Lord Coleridge left it to the jury to decide, and the jury decided that the acts of the defendant Cook were not judicial acts. But the decisions in *Molyneux v. De Burgh* and *Houlden v. Smith* are not "obiter," but are the precedents directly in point. With deference to the *National Observer*, it is, I submit, the decisions against me which are ALL OBITER, no action having ever before been brought against a judge for direct violations of statutes; and I invite the citation and examination of a single case in which the decision in favour of the defendant judge does not rest on the act complained of being within his jurisdiction, or having a colour of jurisdiction.

In this judgment there is, as is known, a further element of doubt, and ground of appeal, in the question of Lord Esher's competency to hear the appeal, there being at the time an action in progress in which he was a defendant (*Yeatman v. Soden* and others) for alleged slander uttered on the Bench in matters *coram non iudice*. If this ground is, as I believe, good, illegality is heaped upon illegality, and I have surely most exceptional grounds to ask for help in obtaining justice. If the case is not elementary, there remains—on such grounds there may well remain—more than a chance—a hope of success in the House of Lords.

It is not unknown for the Divisional Court to be upheld—and for the Court of Appeal to be reversed—and not only I, but all who desire a right of remedy against a blow in the face from a judge, or against other crimes if committed by judges, may well hope that the present may be such an instance. To this right of action—the only thing that has served me so far—I naturally cling. If it is finally decided that I do not—that no British subject does—possess this safeguard, the sense of the nation will perceive that a safeguard must be provided. For this safeguard, for compensation and redress, I can with no derogation or sacrifice of right apply to Parliament, when, but not until, it is finally decided that I do not possess it at law; that I never had the right to maintain this action; that, according to a lame and imperfect constitution, not only I, but a whole colony, lay at the mercy of tyrant judges, of a cruel, indifferent, and irresponsible officialism. It will, I think, be clear that if I have this "RIGHT" I should betray myself and my cause were I to accept in lieu of it, even from Parliament, any mere voluntary concession not to be expected by others. In the like case, who could never be so fortunate as to have a verdict on which to base such an expectation.

In these explanations and in the views I have taken I have endeavoured to follow the views of the committee and to adhere to the lines on which it is proceeding; and I hope that I shall obtain its support in the publication of this reply to misconceptions that I cannot but fear will, if left unexplained, prove fatal to the hope of influential and widespread support.

I have the honour to be, my Lord and Gentlemen,

Your very obedient servant,

54, Bloomsbury-street, W.C., May, 1895.

R. B. ANDERSON.

"A PREVENTIVE OF HYDROPHOBIA."

To the Editors of THE LANCET.

SIRS,—Under the above heading in the current issue of THE LANCET Mr. T. J. Tonkin calls attention to a curious method of treatment prevalent in the Soudan. It may be of interest to mention that a somewhat similar case came under my notice in the province of Shantung, North China, about three years ago. An intelligent native of considerable literary ability called on me to provide him with a remedy, he having been bitten slightly in the hand about six weeks before by a rabid dog. The wound, which must have been very small, had completely healed. I asked what treatment he had already adopted, and he informed me that the dog had been killed, the heart—in this instance—taken out and boiled, and that he had eaten it. He was seen again twelve months later, and had been free from any symptoms of disease. In a country where the whole carcass of the dog is considered a delicacy, this method of therapeutics cannot, perhaps, be regarded as strange.—I am, Sirs, yours faithfully,

WM. W. SHEPESHALL, L.R.C.P., L.R.C.S.E., &c.

Fawcett-street, S.W., May 17th, 1895.

THE SEMILUNAR FIBRO-CARTILAGES OF THE KNEE-JOINT.

To the Editors of THE LANCET.

SIRS,—May I claim a portion of your valuable space to enter a protest on behalf of a pair of structures with which the human knee-joint is endowed, the function of which, mainly as a result of the intrusion of the irrepressible knife of the surgeon, and partly, and in my humble opinion wrongly, on behalf of their possible morphological history, is being minimised and downtrodden?

First, with regard to their history, Mr. Bland Sutton has produced evidence in favour of their origin in connexion with tendons surrounding the joint; but, as far as I am aware, he himself has never advanced this theory as an evidence of their uselessness, and with regard to this point he has much more forcibly demonstrated a similar origin for the internal and long external lateral ligaments, which are generally considered as effective and useful as the lateral ligaments of any other joint. Further, as has always been pointed out, the knee-joint as a whole owes its strength and solidity mainly to the tendons which surround it, bringing these into the closest functional association with the ligaments themselves. The expansion of the quadriceps anteriorly forms the largest and most striking example of the supplementary covering given by tendons to the extensor aspect of a joint capsule, while its connexion to the thin capsular ligament ensures against any dipping in of the synovial lining when the knee is suddenly extended, and its tendon, from its close association with the tibia of the front of the joint, is usually spoken of as the ligamentum patellæ. Posteriorly a similar striking illustration of the utilisation of a tendon as a ligament is offered by the oblique fasciculus of the posterior ligament derived from the semi-membranosus, which places the ligament to a certain degree under contractile power and control when the joint is suddenly extended, preventing the possibility of an instantaneous strain which, if the ligament were an entirely passive structure, would be a source of danger, and also prevents any infolding of the capsule when the position of extreme flexion is assumed.

Secondly, these fibro-cartilages are actually thickened infoldings of the synovial membrane, and with regard to their history a complete transitional series may be traced in different joints of the human body. First let us take the case of the acromio-clavicular joint; here we find the anatomical authors at slight variance as to the presence or not of a fibro-cartilage, the structure in question being a mere infolding of the synovial lining of the upper aspect of the capsule, which varies considerably in size and thickness. In the elbow-joint, as has been pointed out by Professor MacAlister, a miniature meniscus, consisting of an infolding of the synovial membrane, surrounds the margin of the head of the radius. In the shoulder-joint a well-marked meniscus surrounds the margin of the glenoid cavity, here undoubtedly in great part deriving its firm fibres from a tendon, that of the long head of the biceps. In the knee-joint the inter-articular fibro-cartilage as a meniscus reaches its highest development, since it is not a passive ring, but a circular movable cushion, giving elasticity and providing for proper adaptation of the bony surfaces in proportion to the varying areas of the latter which come into direct contact in the different positions of the joint. Here I would refer especially to an additional meniscus, obviously a synovial fold occasionally developed by thickening of the ligamenta alaria; in an instance of this preserved in the Museum of St. Thomas's Hospital the resemblance to a semilunar cartilage was so strong as to suggest to some observers the possibility that it was one of the latter displaced.

Lastly, as to the use of these structures. 1. They do act as buffers, coming into action when the pressure between the bony points in contact is as great as can safely be borne, protecting the central part from injurious pressure just as the tubera ischii are relieved from pressure in sitting on a circular air cushion, and as a single unit in the erect position are as important as an intervertebral disc. 2. They do not "slip forward" when the knee-joint is extended, but are pushed and expanded by the lower end of the femur and the superincumbent weight, and at the termination of extension form an important elastic wedge-check, helping to allow of rapid, complete extension without a sudden strain on the ligaments of the joint. 3. By their firm adaptation to the convex posterior segment of the articular surface of the femoral condyles they enlarge the area against which the head of the tibia plays in internal and external rotation of the flexed joint. 4. They deepen the articular cavity for the femoral condyles in the extended position of the joint, the outer part of the condyles resting on an elastic cushion which fills up the interval which would otherwise exist. Mr. Moullin suggests that the use of the cartilages is to prevent nipping of the anterior part of the capsule. I would only say with regard to this theory that the capsule is, as I have tried to show, provided with muscular attachments such as are seen in other joints to prevent this occurrence; that

the greater part of the anterior aspect is attached to the margin of the patella, which bone moves with the quadriceps, and also tends as a rigid area to prevent folding of the capsule. I may also advert to the fact that the cartilages themselves, which are certainly held between the bones, are invested on both aspects by the synovial membrane. These remarks have been called forth by those contained in a clinical lecture by Mr. Moullin, published in THE LANCET of May 18th, and in a less degree by the fact that during the past session a speaker at one of the London societies gravely suggested that since Mr. Sutton had shown these structures to be in some sense vestigial the knee-joint would be better without them. In writing the above I in no way dissent from the practice of removing broken cartilages, and should always resort to this treatment, but on the other hand I would maintain that the knee-joint without the semilunar cartilages has lost one of its most perfect means of fine adjustment.

I am, Sirs, yours faithfully,
Charles-street, W., May 20th, 1895. G. H. MAKINS.

"KINGSLERE DISTRICT COUNCIL AND MEDICAL REMUNERATION."

To the Editors of THE LANCET.

SIRS,—My attention has been directed to an annotation in THE LANCET of May 4th under the above heading. The reporters were premature in their statement. The appointment (!) was offered to me on Tuesday, the 14th inst., and respectfully declined. I am, Sirs, yours truly,

Kingsclere, May 17th, 1895. REG. MAPLES.

SMALL-POX IN CALCUTTA.

To the Editors of THE LANCET.

SIRS,—Seeing that in Calcutta the deaths from small-pox for eight weeks only of the quarter do really exceed in the ratio of nearly three to one the number of deaths from the same disease in all the capitals of the world put together for a whole quarter, those in Calcutta proper being 872 and in the other capitals for thirteen weeks 333, I should like to ask someone well acquainted with the city the presumable reason. Is there no legal requirement of vaccination, and are there no public vaccinators? Is the Hindoo and Mahomedan feeling against the operation so strong that it cannot be put in force? It certainly does not say much for the operation or its performance if, in our principal colonial city, the disease exists unchecked to the terrible extent it appears to here. Who is to blame?

I am, Sirs, yours truly,
Gravesend, May 20th, 1895. J. H. GRAMSHAW, M.D.

"ARE APOTHECARIES, OLD OR NEW, ENTITLED TO ADVERTISE?"

To the Editors of THE LANCET.

SIRS,—I am also prompted, like your correspondent "Ethica," to reply to his letter. He accuses the holders of the L.S.A. diploma of being advertisers. I have been associated with general practice in London for the last twelve years, and I can honestly say that the majority of advertising cases that I have come across have not been from holders of that diploma. The new L.S.A. is now as fully qualified as anybody; why, therefore, should he wish to advertise any more than an M.D. Lond.? It appears to me that jealousy has a great deal to do with these attacks on the L.S.A.'s. I am in practice in a large London suburb, and three of the most professional men in that district are holders of the L.S.A. I am, Sirs, yours truly,

May 18th, 1895. JUSTICE.

MEDICAL AID ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—I have always been under the impression that THE LANCET would not support in any way any medical aid company or association. Judge of my surprise last week when I beheld an advertisement emanating from the Accrington Medical Dispensary. This is one of those

businesses that of late have been the subject of inquiry by the General Medical Council. For reasons best known to themselves the name of "Medical Aid Association" is gradually being dropped by the committeemen of these businesses, and other names substituted, as "Medical Institute," "Medical Dispensary," &c. For some reason, at present unknown to me, I perceive that in this year's list of medical aid associations the statistics relating to Accrington, showing the numbers, profit, and loss, total worth, &c., were not supplied by the secretary. In conclusion, I may mention that an advertisement for an assistant appeared in THE LANCET about three weeks ago from another association.

I am, Sirs, yours faithfully,
May 21st, 1895. DETECTOR.

* * We do not insert the advertisements of medical aid associations or of like bodies if we have any reason to suppose that they act on objectionable lines, but it is obviously impossible to absolutely ensure the rejection of such advertisements. Our clerks have strict rules to this effect which they carefully follow, but unfortunately they are not all "Detectors." The advertisement in THE LANCET of last week did not on its face appear to contain anything to which exception could be taken. If our correspondent will furnish us with the means which he apparently possesses of infallibly detecting the character of every "Dispensary" we shall be greatly obliged to him.—ED. L.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Assizes.

MR. JUSTICE HAWKINS concluded the criminal business of the Assizes on the 15th inst. with the trial of William Miller for the wilful murder of Edward Moyse on Feb. 19th last. The trial ended in a verdict of "Guilty," such being, indeed, the foregone conclusion. This city has been too often the scene of a brutal murder, and this most recent one offers no extenuating circumstance, but several of great aggravation. The deceased was an aged man who on the fatal night offered the prisoner hospitality and a bed for the night. In the morning at an early hour John Needham, a boy aged fifteen, saw the prisoner rummaging the house, and was suddenly attacked by him and wounded. He defended himself as well as he could, and on the prisoner leaving the house he went and found his master (Moyse) wounded and apparently dead. Needham went for assistance, became faint from loss of blood, and was taken to the Northern Hospital, where he remained for some time. Moyse was found to have been dead some time, and from the state of the body it was evident that he had been stunned while asleep and then killed by heavy blows on his head and face with a hatchet. The prisoner was arrested a few days later and identified by Needham. In addition to this direct evidence there was a long chain of circumstantial evidence against which there was practically no defence, the prisoner being quite unable to account for his movements on the fatal night. Mr. Justice Hawkins passed severe sentences on six women who had inflicted grievous bodily harm on a boy who had been a witness against the husband of one of the prisoners. The prisoners were all respectable charwomen, against whom there was no previous charge, but in this their first offence they had been guilty of wanton violence against a boy who had simply done his duty as required by law. He had been left by them on the road in an unconscious state, and he was in the Royal Infirmary for some time after. The judge awarded severe sentences for other crimes of violence, and observed that drink was the exciting cause of many of them.

Fatal Effects of Tight-lacing.

The city coroner held an inquest on the 15th inst. upon the body of a domestic servant aged eighteen years who was attacked on the 11th inst. with pains in the stomach. She was seen by Dr. McCormick, who found her corset so tightly laced that it had to be broken off. She was taken home and treated, but died on the 12th. At the post-mortem examination an ulcer was found in the stomach, which the medical

man attributed to tight-lacing. It is remarkable how this, like other foolish fashions, dies very hard.

Electrical Communication with Lightships and Lighthouses.

The river Mersey has been the scene of many a wreck and many deaths from drowning. These are not due to any lack of courage on the part of the lifeboat men, who are only too ready to risk their own lives. The Royal Commissioners have recommended that the Formby Lightship shall be connected with the shore by means of an electric cable, which will enable the crew to communicate promptly by telephone the exact position of any vessel in distress and so save valuable lives. They will also be able to call for medical aid when this is required.

Hospital Saturday.

Saturday, the 18th inst., was observed as Hospital Saturday in the city. A new departure was made this year by a number of ladies, who paraded the streets from an early hour, collecting contributions from the large number of passers-by. The number of persons who enter the city from all points of the compass every week-day is marvellous, and it is to be feared that only a very small proportion contribute anything to the medical charities. This new arrangement has, therefore, at least something to be said in its favour. The amount accruing from the Hospital Saturday Fund has steadily increased since its commencement in 1870, and a large increase is looked for this year.

Deaths of two Liverpool Surgeons.

Within a very short period two members of the profession who formerly practised in Liverpool have passed away, each having passed the age of fourscore. The first, Mr. Richard Hutchinson, died at Heswall, Cheshire, where he had been living in retirement for some years past. Mr. Hutchinson became a Member of the Royal College of Surgeons of England in 1837, and had for many years a large practice, being also honorary surgeon to the South Dispensary. The other gentleman was Mr. John Nottingham, F.R.C.S., who was honorary surgeon to the Southern Hospital for many years and had a considerable reputation as a surgeon and general practitioner. For some years past he had lived in retirement at Whitchurch, Salop, where he died.

May 20th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle-upon-Tyne Eye Infirmary.

At the annual meeting of this valuable charity, recently held in Newcastle-upon-Tyne, Dr. C. S. Jeaffreson, the honorary house surgeon, called attention in his report to the number of patients treated in the out-door department whom he considered to be "not fitting recipients of charity," many of whom he said were "in receipt of large wages." If the complaint thus publicly made be correct, and it is not by any means the first time that Dr. Jeaffreson has made it, the charity is undoubtedly being grossly abused. The financial statement was not altogether satisfactory, and one would think nothing would tend more to alienate support than the repeated statements by a responsible officer that the charity is abused. The Eye Infirmary is a very perfectly arranged and equipped hospital doing a great deal of excellent work, and it is much to be regretted that it should be made use of by a class for whom it is not intended. Some means of checking abuse at this as well as at other similar institutions should be possible.

Society for the Prevention of Cruelty to Animals.

At the annual meeting of this admirable society, held recently at Newcastle-upon-Tyne, Colonel Coulson said that "a few days ago, while he was in the south of England, a man brought a very beautiful little dog to a friend of his for sale. Enraged because he could not sell it the man took his dog into a wood and there skinned it alive." It seems almost incredible that such a thing could have happened in England, but Colonel Coulson added—"the man was arrested and sent to prison for two months, with hard labour, by the magistrates." This was received with applause by his audience, though why it should have been it is difficult to explain. The punishment was about the same as is not infrequently awarded to some homeless wretch for sleeping out

or to a poacher for stealing a hare. Surely penal servitude would not have been too much for such an offence. Colonel Coulson suggested that a Bill should be brought in permitting judges and magistrates to flog men for acts of gross cruelty to women, children, and animals, and he added that he himself would be quite willing to flog such offenders free of expense to the Government. It is quite time such an Act was passed. The argument that the lash would degrade a man capable of skinning a live dog is absurd. How could such a man by any means be degraded? On the contrary, to flog him soundly would be the sole means of appealing to any feeling he possessed which was capable of responding.

Health Exhibition.

The sum of £105 has just been divided by the Mayor among the medical charities in Newcastle-upon-Tyne, the proceeds of the first day's receipts at the Health Exhibition now being held in Olympia. Mr. Engel, the manager of this very successful and interesting exhibition, deserves the thanks of the charities which his enterprise and kindness have benefited.

Newcastle-upon-Tyne, May 21st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

A Hospital Caravan for Infectious Diseases.

A NOVEL departure in providing for the isolation and treatment of infectious cases has been adopted by the local authority in one of the districts of East Lothian. It consists in having a movable hospital in the form of a caravan. The caravan has four wheels and can be drawn by two horses; it has an air space of 1520 cubic feet, being 19 feet long, 10 feet high from floor to roof, and 8 feet wide. It has double walls, with an intervening space of one and a half inches. One end of the caravan can be dislodged to allow of the vehicle being placed corridor fashion against another. Each van has two beds, and is thoroughly equipped. It is proposed to provide a tent with each van for the nurse or for cooking. The cost of each vehicle is £100. The advantages claimed for this novel method are that the van can be taken to the patient, and that the vans in the several districts can be brought together wherever an outbreak of infectious disease occurs. The local medical man would have charge, and it is thought that the system will be an economical one. The originator of the idea was Mr. James Wyllie of Pathhead, the brother of the senior ordinary physician to the Royal Infirmary.

Edinburgh Royal Infirmary.

At the meeting of the managers of this institution on Monday a letter was read from the clergyman on the Island of Foula enclosing the sum of £1 5s. 6d. from the islanders as a contribution to the funds of the hospital. This humble recognition of the services rendered by the Royal Infirmary might be taken to heart by many who have more of this world's goods than these poor and isolated people have. If we mistake not the clergyman not only acts as the spiritual guide of the people but also as their medical guide, and takes charge of them at both ends of life.

Glasgow Samaritan Hospital for Women.

The foundation-stone of this hospital was laid on the 18th inst. by Lord Blythswood. The ceremony was performed with Masonic honours, and was witnessed by a large gathering of the profession and the general public. When completed the hospital will provide accommodation for twenty-eight patients. There will also be a lecture-room for students, and the necessary administrative buildings and nurses' home. The estimated cost of the building is £8000, in addition to which a further sum of £1500 will be spent on furnishing. The present hospital is small and unsatisfactory in many respects, so that the new hospital will be a useful addition to the charitable institutions of the city, and will still further increase the clinical resources of the Glasgow Medical School.

Glasgow University.

One of the earliest and most impressive experiences of the Glasgow undergraduate is the dignified and important bearing of the Bedellus and Janitor as he carries the University

made in front of the Senatus at some official academic ceremonial. And one of the latest, and certainly not the least pleasing, recollection of college life is the action of the same official as he, immediately after the ceremony of "capping" has been performed, throws the hood, indicating the possession of a degree, over the shoulders of the newly-fledged graduate. These experiences for the past forty-two years have been associated with the genial personality of Mr. Lauchlan Macpherson, and there will therefore be Glasgow graduates in all parts of the world who will be interested to hear that Mr. and Mrs. Macpherson have recently celebrated their golden wedding amidst general congratulations both from town and gown. On the occasion of the anniversary Principal Caird, in the name of the Senatus, presented the worthy pair with a purse of fifty sovereigns, an extra shilling being added "for luck." During the forty-two years of Mr. Macpherson's college experience the whole of the professoriate, with the single exception of Lord Kelvin, has been changed, several of the chairs, indeed, having been vacated two or three times. Queen Margaret Hall, the residence for women students, is to be enlarged by the erection of an additional storey.

Broomhill Home for Incurables.

In December, 1893, a very successful bazaar was held in Glasgow in aid of the funds of this institution, and a sum of £10,000 was raised. Part of this money has been spent in the erection of a new wing to the home, and this was formally opened on the 18th inst. by her Grace the Duchess of Montrose. The new wing provides accommodation for the nurses and servants, with the necessary rooms and offices for the matron. The remainder of the money is to be used partly to meet the annual deficit on the working of the institution and partly to aid the building fund of a new home for imbeciles which it is proposed to erect.

Glasgow Ear Hospital.

The annual report submitted by Dr. Barr at the meeting of subscribers on the 15th inst. showed that sixty-eight in-door patients had been admitted during the year, whilst 1121 out-door patients had been under treatment; the number of operations was fifty-two. As a result of the class examinations, prizes were awarded to Mr. Wm. Lawson and Mr. Archibald Young. The financial position of the hospital is an eminently satisfactory one.

The Sale of Ice-cream.

In the new Police Bill, promoted by the corporation of Glasgow and at present before a committee of the House of Commons, a clause giving power to control the sale of ice-cream and to inspect and regulate the shops in which it is made has been introduced. The necessity for this is manifest when it is considered that there are no less than 286 such shops in the city and that in a large proportion of these the ice-cream is really made in the sleeping apartment behind the shop. Moreover, those engaged in the trade are for the most part foreigners with somewhat primitive notions of cleanliness. In a neighbouring town a serious outbreak of enteric fever was traced to one of these ice-cream establishments.

Glasgow Medico-Chirurgical Society.

The following are the office-bearers for the session 1895-96 of the above society:—President, Dr. Wm. L. Reid. Section of Medicine: Vice-president, Dr. Finlayson; councillors, Dr. James W. Allan and Dr. R. B. Ness; secretary, Dr. Hinshelwood. Section of Surgery: Vice-president, Dr. A. E. Maylard; councillors, Dr. James A. Adams and Dr. J. Walker Downie; secretary, Dr. John Barlow. Section of Pathology: Vice-president, Dr. T. K. Monro; councillors, Dr. L. R. Sutherland and Dr. J. Lindsay Steven; secretary, Dr. R. M. Buchanan. Section of Obstetrics: Vice-president, Dr. Samuel Sloan; councillors, Dr. George Halket and Dr. J. Nigel Stark; secretary, Dr. E. H. Lawrence Oliphant. Treasurer, Mr. Henry E. Clark; general secretary, Dr. C. O. Hawthorne. The society has passed a special vote of thanks to Dr. Walker Downie for his services as general secretary during the past six years.

Hartwood Lunatic Asylum.

This asylum, which has been erected for the Lanark district lunacy board, was opened on the 14th inst. by Sir Windham C. Anstruther, the chairman of the board, in the presence of a number of medical and other gentlemen interested in the care and treatment of pauper lunatics. The buildings are

on a very extensive scale and have occupied five years in erection. The medical superintendent is Dr. Campbell Clark.

District Nursing in Sutherlandshire.

To promote the appointment of district nurses in the county of Sutherland a meeting was recently held at Dunrobin Castle under the presidency of the Duchess of Sutherland. A number of the medical men from various parts of the country were amongst the 400 ladies and gentlemen who attended, and the necessary steps were taken to secure nurses, some of whom, it is hoped, will commence work immediately. It was also decided to hold a bazaar to promote the success of the scheme.

May 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Telephonic Communication in Dublin.

DUBLIN is so circumstanced as regards the position of its chief hospitals and the dwelling-houses of the medical men, and more especially of the surgeons who constitute their visiting staff who live in many cases some miles away, that the telephone is largely made use of by them. Much dissatisfaction has been caused recently by the failures of the present system, managed as a branch of the National Telephone Company. The snowstorms of February caused an almost complete breakdown, which state of things prevailed for about six weeks, while ever since accidental contacts of wires and failures of communication have been both frequent and annoying. Many letters of complaint have appeared in the daily papers, in one of which, addressed to the editor of the *Irish Times*, a proposal is made by the writer, who signs himself "A Merchant," to establish an independent company. This, he says, has been done successfully by the merchants of Manchester, where a similar state of things prevailed. Such a strong measure will not, I trust, be required here; but it is certainly very annoying to surgeons to find their messages, which are usually few but of importance, lost or delayed in transmission.

The Small-pox Notification Case.

This case still causes much public interest in Dublin. The *Irish Times*, in a leading article on the 18th inst., alluding to a letter from Dr. Cruise, Vice-President of the Royal College of Physicians of Ireland, says: "The letter of Dr. Cruise, as coming from one of the most eminent and universally respected members of the profession, will receive general consideration. 'It is the interest of the public,' he says, 'to support Dr. Hadden, because the recent verdict is a death-blow to notification.'" Dr. Hadden's solicitors, in a letter to the same journal, announce to-day (the 21st inst.) that they have served notice of motion to have the verdict set aside and judgment entered for the defendant, or alternately for a new trial of this action. The action has also occasioned considerable discussion amongst medical men in the north of Ireland; and on all sides there is the utmost sympathy for Dr. Hadden. In Belfast, where the Notification of Infectious Diseases Act has not yet been adopted, those medical men who were in its favour feel that after such a verdict as has been given in the Dublin case they must use every effort to prevent the Act being put in force. The issue of the trial is felt by everyone to be a blow to preventive medicine. The following is a copy of a resolution passed by the council of the Irish Medical Association on May 20th:—

"That the council of the association, upon consideration of all the circumstances set forth in the evidence submitted to the court in the case of *Mason v. Hadden*, is of opinion that the course pursued by Dr. Hadden was such as was imperatively imposed upon him by the Infectious Diseases Act, and that his duty so imposed was discharged with due care and discretion. That the council, therefore, expresses its earnest sympathy with Dr. Hadden in the position in which he has been placed by a conscientious endeavour to perform his public duty; and, furthermore, regard the decision in this case of great importance and fraught with the most serious consequences to the public, as it must have the effect of causing the notification of these diseases to be delayed until they shall have so far developed as to be extremely dangerous to the health of the community."

Sir Patrick Dun's Hospital, Dublin.

The *Ierne fite* in aid of this old-established hospital was opened this afternoon (the 21st inst.) by his Excellency the Lord Lieutenant.

Respirators in Mills.

The attempt by the authorities to force the operatives in

the Belfast spinning mills who are eighteen years of age and under to wear respirators while at work has given rise to a great deal of writing in the public press and to a lively discussion in business circles, all the more as the linen industry is one of the great features of the commercial capital of Ireland. The workers object to these respirators because after being used for a time they become so clogged with dust that they impede respiration, and they get so filthy that they are practically unbearable. I have examined these respirators, which are made of cellular material lined with wool and are fastened round the head with elastic bands, and certainly after being used for a time they become very uncomfortable. When a question was asked in the House of Commons by Sir John Lang about these articles the Home Secretary said they could be washed; but anyone knows that the workers who object to them will not take this trouble, and so the onus is thrown on the mill proprietors, who naturally demur to spending money in this way when they see that their employes are so opposed to wearing the respirators. Then another reason against their use is that the order to wear them does not apply to all, the hacklers and roughers not being included, and practically it comes to this, that these "muzzles," as the workers call them, are simply worn round the necks ready to be slipped over the mouths should the inspectors enter the mills. The general opinion is that it would be much wiser to insist on thorough ventilation of the work-rooms, if necessary by forced draughts, and not to urge the constant wearing of these respirators, a plan which, in order to be carried out, would need all the police and detectives in Belfast to be stationed in the mills, and which those really conversant with the trades carried on in the mills and who are most anxious to do everything to prevent disease look upon as an utterly unworkable and impractical method.

The Dundalk Workhouse.

At a meeting of the Dundalk board of guardians, held on May 20th, a letter was read from the Local Government Board, in reply to a resolution of the guardians asking for a sworn inquiry into the causes of failure of the extensive sewerage system recently constructed by the board, to the effect that it was not a matter for them to hold an inquiry into. A letter was also read from a gentleman calling on the guardians to stop the passage of sewage into the defective sewer, to empty and disinfect the pipes, and to so dispose of the sewage of the workhouse as no longer to contaminate his grounds or the roadway alongside. The guardians directed that the steps asked by this gentleman should be taken and adopted a resolution, proposed by Dr. MacDonnell, to the effect that the interests of the ratepayers demand a searching inquiry by a competent authority into the failure of the sewer, recently constructed at a cost of £1100, to fulfil the functions for which it was contemplated; that the sanitary state of the house is at present in a deplorable condition owing to the failure of the drainage plan; and that the guardians, being unable to come to any decision without ascertaining where the faults of construction rest and who is responsible for the failure, request the Local Government Board to reconsider their decision not to hold a sworn inquiry.

Technical Education in Ireland.

At meetings of the Newry and Bangor Town Commissioners, held on May 20th, resolutions were passed in reference to technical (including agricultural) education in Ireland and approving of the need of its proper endowment by the Government.

The Royal University M.B. Examinations.

At the recent M.B. examinations of the Royal University of Ireland every candidate in the upper pass division was from the Belfast Medical School, and out of these two were recommended for the further examination for honours.

The Weather.

For the past week we have had very cold stormy weather in Belfast, and there has been a return to winter clothing. It is now milder and rain has set in with a cessation of the wind.

The Battle of the Clubs at Cork.

A meeting was held last Friday for the purpose of making presentations to two secretaries who, as paid officials of clubs, naturally enough offered strenuous opposition to the medical men's organisation. The meeting, though ostensibly convened to give publicity to the presentation, was in reality intended to stimulate the waning enthusiasm of the clubs. The chairman of the meeting is a buldier, who can point to the graceful spires of one of the city cathedrals as indications

of his prosperity, and it is hardly surprising that the Cork profession should object to his being in a position to procure for a paltry fifteen shillings medical attendance and medicines, not alone for himself, but for his whole family from year's end to year's end. To one of the secretaries he presented what he described as "a magnificent gold watch." To the other he handed a purse of sovereigns, but displayed a reticence in not mentioning the number of gold pieces contained in the purse. After the usual amount of harmless abuse had been indulged in a member took occasion to mention that it was not true that one of the imported medical men intended to leave the city. Be that as it may, it is quite certain that the fact of the Cork medical men objecting to meet the newcomers either professionally or socially is producing its effect.

The Irish Queen's Colleges and the "65" Rule.

The Treasury has with varying success endeavoured to apply the "65" Civil Service rule to the Queen's Colleges. When the late Government was in power communications were sent to the Cork, Belfast, and Galway Colleges to the effect that as far as the application of the rule was concerned those institutions would be regarded as departments of the Civil Service. The corporate body of each College determined to oppose such a startling innovation, and memorials were drawn up pointing out that the Colleges were entirely different from the ordinary public offices under Civil Service control. A clerk entering the Civil Service is generally a boy aged eighteen, whilst a professor at the time of his appointment has usually arrived at mature manhood, and as the pension is in proportion to the number of years served it is evident the professor and the clerk on arriving at the age of sixty-five would be in entirely different positions, the arithmetic being wholly in favour of the clerk. No doubt it could be urged that professors, once they arrive at sixty-five, ought to make room for younger men who possibly are more in touch with the progress of science, but a well-trained mind at that age is quite capable of grasping new ideas, and the matured experience of such men with regard to the internal administration of a college is often invaluable. Besides that, the statutes of the Colleges afford ample opportunities for getting rid of any men who, owing to declining years or from any other causes, are becoming "luggers on the way." Professors may be regarded as specialists in their subjects. Pension the professor of Greek or the professor of natural physiology at sixty-five, and, no matter how vigorous he may be in mind and body, what can he turn to? The pension calculated on comparatively few years' service must necessarily be small; fixity of tenure is gone, and after spending the best years of his life in the service of his college and his country he arrives at a green old age embittered by penury and by the reflection that scholarly acquirements cannot attain their legitimate price. Moreover, the Colleges rely on their Charters. The professors have been appointed by sign-manual of the Queen to hold office during Her Majesty's pleasure—that is to say, they assert, as long as they are capable, willing, and able to discharge the duties of the high offices with which Her Majesty has entrusted them. The Irish law officers of the late Government on being appealed to decided that the "65" rule could not apply to the Colleges. The English and Irish law officers of the present Government hold that it does. The Chief Secretary referred the "policy" of the application of the rule to the Colleges for the consideration of the Lord Chancellor of England, and that high functionary has recently decided against the contention of the Treasury. The most recent development has been that a Treasury committee, of which Lord Playfair is a member, has expressed a desire for a conference with the three Presidents and one or more professors of the Colleges for the purpose of discussing the whole subject. Meantime President Moffit of Galway College, who was dismissed under the application of the rule, has been reinstated, and Professor England of Cork has a very substantial claim against the Government, as his chair has been transferred to another.

May 21st.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Italian Hygiene and the Travelling Public.

THE tourist season now closing has in point of numbers been inferior to none of its predecessors. Nay, if the spring weeks only be considered, the influx of *forestieri* has been

larger than has for many years been known. This is a great fact for Italy. According to an estimate arrived at some three years ago by the English-speaking Consuls, the annual sum poured into the country by the British, colonial, and American visitors, migratory or resident, is not less than £20,000,000 sterling, almost a third of the public revenue. This money, moreover, is contributed in gold, for which Italy gives an equivalent in her depreciated paper currency. Any cause which lessens this contribution from without is looked upon by Italians as a public calamity, the incidence of which may be realised by a single concrete example. Some years ago there was, without adequate foundation, it is true, a fever scare in Tuscany, which acted as a deterrent on the foreign visitor. In Florence, at the great picture gallery of the Uffizi, the receipts for entrance money (1 fr. per head) were in the first three months of the year 16,000 fr. less than in the corresponding period of the year before. In other words, Florence had 16,000 fewer visitors. How disastrous this proved to the city and its inhabitants may be estimated by the anxiously sustained endeavours since made to raise its sanitary credit and to attract, not repel, the stranger within its gates. These endeavours have not been without their reward, and rarely indeed has Florence, or for that matter the great artistic or otherwise interesting centres, entertained a goodlier number of visitors than has been the case recently. It is only when the tourist leaves the well-worn track, where the demands of civilisation in food, drink, lodging, drainage, and other primary conditions of health are fairly well responded to, that he feels the essentially mediæval character of the Italian *modus vivendi*. In time, no doubt, the rural standard in these matters will be brought up to the urban; but meanwhile the foreign resident in the smaller provincial towns has to put up with a great deal in the daily life that is rough, not to say revolting. To go no further than the food, he must be constantly on his guard, and would do well to practise the safe rule of requiring as little as possible beyond what the natives themselves consume. Take them out of their limited round and the traveller will simply be courting disappointment, or worse. Let me give an artist's experience. This gentleman was on a sketching tour in the picturesque towns on the Roman-Neapolitan frontier, and he had provided himself with introductions to the syndics of three or four *paesi*. These functionaries found lodgings for him; but, in each case, he had to leave next day, having spent a sleepless night in paying an involuntary blood-tax to myriads of bed-fellows. At length he settled down in an unpretending *locanda* in the Sabine country where he could indulge "tired nature's sweet restorer" unmolested. But the daily food was the difficulty. Beyond eggs and poultry mine host could give him little or nothing, though he was persistent in his demands for the chop of British partiality. One day, however, he found before him at *colazione* a smoking dish of mutton cutlets, but to the surprise of the landlord he sent them hurriedly away. "How is this?" was the remonstrance, "you have been asking this week past for mutton, and when with great difficulty we procure it for you you won't look at it." "Yes," was the quiet rejoinder, "but I saw the sheep lying dead on the road this morning." Indeed, you are seldom sure of the origin or "previous history" of the viands set before you in such places, and to judge from the instances of ptomaine poisoning from meat of more than dubious quality even the greater cities are not above suspicion. We far too often read of horseflesh, and that of an unsound kind, being impounded by the sanitary officers at the butchers' shops or in the sausage manufactories, while the seizure and destruction of mushrooms unfit for consumption is constantly recorded in the police columns of the newspapers. Poisoning from the use of non-edible fungi is one of the most frequent causes of disease and death in the inland districts and even in the towns; in the former, indeed, the local *dispensari* kept up by Government for the pharmaceutical service of the countryside are constantly running short of the regulation antidotes. Here, again, we come upon another drawback to the safe residence of the foreigner in Italy. The native pharmacists are not so particular about the renewal of their stock as more civilised usage requires them to be; and, in point of fact, the Government inspectors, whose duty it is to see that the quality of the drugs sold to the public is in all respects "up to date," have been recently reminded even in the lay press (particularly of Southern Italy) that greater vigilance on their part is eminently required. Still, unsatisfactory as in many

cases the food and drink and drug supplies of Italy are apt to be, vast strides in the sound sanitary direction have been made, even in the few years since Bertani's hygienic code has become law. This, if rigidly enforced, as I am happy to say it generally is, coupled with a steadily growing conviction in the landlord class that "honesty is the best policy," and that the English-speaking *clientèle* after which it hankers is mainly to be conciliated and extended by attention to the decencies of civilisation, will gradually bring Italian life up to the higher European standard and find its reward in a larger and steadier proportion of that "foreign import" which (as already indicated) brings into the kingdom even now about a third of its annual revenue.

Organised Quackery.

One must have been a resident in rural Italy to appreciate the difficulties with which the profession has to struggle. Prominent among these are the "falsi sanitari" (unqualified practitioners), who are as prolific as unsound mushrooms, particularly in the southern provinces. The Questore of the "Ordine de' Sanitari" (the Order of Duly Qualified Practitioners), whose surveillance extends over Naples (city and province), has just had to issue the following: "The irregular physicians and surgeons in Naples, at a meeting assembled to devise measures for eluding the action of the authorities in suppressing their illegal 'industry,' have resolved 'no longer to sign prescriptions, or only to sign them illegibly; to affix a date much anterior to that at which the prescription is penned or not to date it at all.' Such tactics (proceeds the Questore) I make known to the public, so as to put it on its guard and to make it insist on exacting from every physician, little known or not known, his signing his prescription clearly, and his affixing to it the proper date. In case of doubt the public is requested to forward to the secretary of the 'Ordine de' Sanitari' the prescription in question, when the Questore will at once institute inquiries. The Questura (agency of the 'Ordine') has drawn up a list of the pharmacies resorted to by unqualified practitioners, where their prescriptions are compounded. These 'pharmacies' are now being watched and made known to all associates of the 'Ordine de' Sanitari' in order that they may assist in accumulating the evidence required by the authorities. Associates are further requested not to relax their vigilance over these 'pharmacies' and to continue to inform the Questura of whatever new establishments of the kind the unqualified practitioners avail themselves of. Their information may be anonymous. The officials of the 'Ordine' will make themselves responsible for the action taken." Ignorance on the part of the population where every one in three is "analfabeto" (unable to read or write) explains the success of these irregular practitioners, belief in witchcraft still prevailing in many of the southern provinces, and the miracle-monger exercising his *métier* too often with the connivance, or at least without the remonstrance, of the lower clergy. Moreover, a better system of medical instruction and graduation must be introduced before the duly qualified practitioner can always count on that respect which is due from the public to the profession. No man has seen more clearly, or more poignantly deplores, the defects and results of that system than Dr. Baccelli. In his capacity as Minister of Public Instruction he has much in his power in the way of reform or of wholesome innovation, and his promised Bill for the Amendment of the Italian Universities, to be laid before Parliament after its reassembling, is awaited with interest by every faculty—by none more keenly than the medical.

Typhoid Fever in the Romagna.

The return-wave of tourist travel which, proceeding from Naples and Rome, is apt to diffuse itself over the interesting towns on the Adriatic seaboard from Ancona to Venice should be warned against the insanitary condition of those centres of population, particularly in the matter of water-supply. I hear from Cesena that within the month now passing fevers of a distinctly typhoid character, often attended with hæmorrhage from the bowels, have been epidemic in the town and neighbourhood. The hospital is full of such cases, children being the most often affected. Sanitary investigation has at once traced the disease to the water, the pollution of which is scarcely more marked in Cesena than in other places in the Romagna. The authorities are enforcing the use of water previously boiled in all the schools, and they are supplying it gratuitously

to those and similar institutions, while an urgent appeal is made to the heads of households to observe this well-timed precaution. By order of the same authorities those certified as having succumbed to the disease are buried "*senza accompagnio funebre*" (without funeral accompaniment), a regulation which furnishes some notion of the alarm caused by the epidemic.

May 18th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Supernumerary Spleens.

DR. ALBRECHT, assistant to Professor Weichselbaum, exhibited at a recent meeting of the Vienna Medical Society an anatomical preparation which contained an enormous number of spleens. Cases of supernumerary spleens are not rare, but in this instance the number of them is extraordinary. In the usual situation there is a spleen the size of a walnut, with the splenic artery and vein in their normal position. The other spleens are dispersed not only on the mesogastrium, but also on the peritoneum, as, for example, on the hepatic ligament and on the convexity of the liver; the largest number were found on the mesentery and transverse mesocolon; there were more than thirty in Douglas's pouch. All these formations are characterised by red colour and pulp, and that they are composed of spleen tissue was proved by microscopical examination. Each spleen is enclosed in a separate capsule and covered by the peritoneum. Professor Toldt sought to explain this abnormality by a reference to comparative anatomy and embryology. Comparative anatomy, however, offers no analogy in the series of vertebrates, the spleen being generally developed in the mesogastrium. Appealing to embryology, Professor Toldt supposes the epithelium of the coelom to form the splenic tissue. The case may be explained on the theory that, besides the mesogastrium, other parts of the coelom may be capable of forming splenic tissue. Professor Weichselbaum suggested an investigation with a view to discover whether these dispersed spleens had performed the function of a normal spleen, and if they had not, then what organ had been the vicarious one. As it is in the spleen that formation of the white and destruction of the red blood-corpuscles normally take place, it is interesting to note that in this case the lymphatic glands of the retro-peritoneal space were increased and that the spleens contained a considerable aggregation of pigment, due to the imperfect removal of the pigment resulting from the destroyed red blood-corpuscles.

Multiple Thrombosis.

At the same meeting Dr. Gruss exhibited a case of Multiple Thrombosis following influenza, nothing similar to which has hitherto been recorded. The patient, aged forty-one years, fell ill some six months ago with symptoms of influenza. Pleurisy with effusion occurred on the left side. At the end of the first week of the illness a tense and painful tumour appeared under the left costal arch, suggesting by its characteristic furrows and other circumstances a tumour of the spleen. On Jan. 9th sudden thrombosis of the left cephalic vein occurred, together with swelling of the upper arm and neck, and after a few days there was thrombosis of the thyroid vein. Then thrombosis of the pharyngeal veins appeared, and at the present moment the veins of the mucous membrane of the mouth resemble an injected preparation. The urine contained red blood-corpuscles and 0.5 per cent. albumen. In the absence of any precise symptom of nephritis that appearance is to be explained by thrombosis of the kidney. The attack of influenza, in fact, caused universal thrombosis, and the tumour of the spleen was due to thrombosis of the splenic vein.

Antitoxin Treatment in Croatia and Slavonia.

From August, 1894, to January, 1895, antitoxin injections have been employed in 428 cases, of which 382 recovered and 46 died, the latter chiefly among the severe cases or those where injection had been made after the lapse of a week; the mortality therefore amounted to 10.8 per cent. Of 826 children treated with prophylactic injections, only 17 fell ill, and among those there was but 1 death, equivalent to a mortality of 0.2 per cent. The average mortality from diph-

theria since the use of antitoxin has therefore fallen from 65 per cent. to 10.8 per cent.

A New Anti-syphilitic Remedy.

Dr. Rille, assistant to Professor Neumann, has published his observations upon the new remedy, hæmolum hydrargyri-iodatum. This is one of Kobert's blood preparations, containing 13 per cent. of mercury and 28 per cent. of iodine. Hæmol, its basis, is obtained by mixing neutralised blood of warm-blooded animals with water and zinc powder. It is to be preferred to all other mercurial preparations, for it produces but trifling salivation without any of the fetid pus of mercurial stomatitis. A case of periostitis of the parietal bone and of the spinous processes of some dorsal vertebrae healed under its use within thirteen days; and a case of perforation of the hard and soft palate was decidedly benefited. As it contains iron it possesses also tonic properties, and may be regarded as a very valuable remedy against all cases of syphilis complicated with pallor or scrofula. The dose is 0.8 gramme (= 13 grains) daily.

Professor Dittel.

This Nestor of Austrian surgeons celebrated his eightieth birthday on May 15th. It is worthy of mention that during the last five years he has performed 500 lithotomies and has published some important works, such as "*Treatment of Recto-vaginal Fistula*," and "*Foreign Bodies in the Urinary Bladder*" (together with a new operative method). The octogenarian professor is an entirely self-made man, who has obtained his honourable position by energy and indefatigable pursuit of knowledge.

The Obstetrical Congress.

The Sixth Congress of the German Obstetrical Society will take place at Vienna on June 4th, 5th, and 6th. The two subjects to which special attention will be directed are Endometritis and Rupture of the Uterus.

May 19th.

Obituary.

JOHN CRERAR, M.R.C.P., L.R.C.S., I.M. EDIN.

By the death of Mr. Crerar the town of Maryport in Cumberland has lost its oldest practitioner. He was of Scottish origin, and his first introduction to the district was about thirty years ago. The industry of West Cumberland was then entering on its prosperous years, and he rapidly acquired an extensive practice, which was at one time among the largest in the north-west of England. Few men have lived a more busy life or have been more devoted to incessant work. He was, moreover, a man of very considerable linguistic attainments, being a good classical scholar and well read in Celtic literature. His was no mere superficial knowledge, but was that of the cultured philologist, kept up to date and in touch with modern scientific developments. He was an excellent speaker and took a prominent part in public matters both on religious and secular questions. He was a firm and unchanging friend, a fearless but just and honourable controversialist, and a man of purest life and noblest aims. His appearance denoted marked individuality. An ample forehead, bushy eyebrows, clear grey eyes, a bearded face, a spare, slightly stooping frame, and a quiet, thoughtful way of speaking all combined to denote a self-reliant and intellectual character. Mr. Crerar was an original member of the Border Counties Branch of the British Medical Association, and filled the offices of president and vice-president. The treatment of influenza interested him deeply and formed the subject of papers contributed by him to THE LANCET.¹ His last illness was the result of a cardiac breakdown, and the end came on May 11th, bringing to a close in its sixtieth year a life for which a considerably longer duration might have been anticipated.

ALFRED WILLIAM STURDEE, L.R.C.P. LOND.,

M.R.C.S. ENG.,

OF H.M.S. "HOOD."

It is very painful to have to record the death of this young naval surgeon from drowning while bathing at Gozo, near

¹ THE LANCET, Dec. 19th, 1891; Feb. 3rd and 10th, 1894.

Malta. His name will be familiar to the teachers of the London Hospital and to the *alumni* of that school who qualified three or four years ago. Mr. Sturdee's career was entirely pleasing and promising. Born at Sheerness on Nov. 27th, 1869, he was the son of the late Mr. Alfred Barrus Sturdee, Chief Constructor of H.M. Dockyard, Devonport, who lived at the time of his death in Highbury. Young Sturdee early began to distinguish himself. He took the first prize at Mannamede School at Plymouth in 1880. In 1884 at the Tonbridge School he took the prize for French. He studied medicine, as we have indicated, at the London Hospital, where he made his mark in the prize lists for dressing, for dissections, &c. He was also, we believe, assistant demonstrator in the physiological laboratory. After taking the double qualification in London, he proceeded to examination for an appointment in the Royal Navy, in the direction of which all his aspirations went. He came out in the first place. In 1891 he went to Haslar, and in 1893 he was appointed to H.M.S. *Hood*, in which to the time of his premature death he was known as a most useful and agreeable officer. His French stood him in good stead, and in the Greek villages and places which his ship visited he showed an unusual facility of learning their language. His kindness to everybody was felt. He had passed the first part of the examination for the Fellowship of the Royal College of Surgeons, and everything promised a brilliant career in the service which he so much loved when news of his being drowned while bathing reached his family from the Admiralty. Since then news has been received of his funeral. We are permitted to make the following extract from a letter from the chaplain of his ship, and with this quotation we close our notice of a life all too short, but which has made a deep impression on all who came within its influence, and the loss of which to his mother and brothers and sisters is inexpressible:—

"At the funeral, which I conducted, there was a larger attendance of officers and men than I ever recollect seeing. Beautiful wreaths were sent by his own ship officers and men, each sending one, and by other friends, but there was one wreath that would interest you more than the rest. It was placed on the grave by a little boy of eight, and was composed of lovely flowers wrought into the shape of an anchor. I found that he was the little boy whose leg—very badly fractured just before Christmas—was perfectly restored by the skill and devotion of your son, so that the little fellow could walk without lameness or any sign of an accident. We were away from Malta since Dec. 27th, but on our return your son's first visit was to his little patient to see if his recovery was complete. The gratitude of the boy and his parents knew no bounds, and their sorrow found expression in the gift of this beautiful wreath."

JAMES STEDMAN CRAIGIE, M.D., C.M. EDIN.

DR. CRAIGIE died on the 16th inst. He was an M.D. of the University of Edinburgh (1884) and also B.Sc. in Public Health (1888). He held the appointment of medical officer of health of Musselburgh and was one of the deputies of the county of Midlothian, the duties of which he fearlessly carried out under many difficulties on the adoption of the Public Health Act, clearing away many of the slums in the burgh. During his long illness he was the subject of much solicitude on the part of the community which he served so well. Apart from his high professional qualifications, he had great linguistic and literary faculties. He was the author of some of the principal medico-biographical articles in the last edition of "Chambers' Encyclopedia." He was also well known in musical circles in Edinburgh as an accomplished violinist. Those who knew him privately had learned to recognise in him, in addition to many other qualifications, a faculty for dealing with things generally in a broad and unconventional spirit.

HUGH FRANCIS CLARKE CLEGHORN, M.D., LL.D., F.R.S.E., J.P.

DR. CLEGHORN, who died at Stravithie, Fifeshire, on May 16th, had passed the most active years of his life in the Indian Medical Service, and was a distinguished authority on Indian botany and arboriculture. He was born in Madras in 1820, and received his education in Edinburgh and at St. Andrew's University. He was for some time a pupil of Professor Syme, and one of the house surgeons in

the Edinburgh Royal Infirmary. He graduated in 1841, and thereupon returned, at the age of twenty-two, to Madras, where he was appointed Professor of Botany about twelve years later. In 1855 he was requested by the Governor of Madras to organise a Forest Department having for its object the preservation of tree life, and in course of time he was appointed one of the Commissioners for the Conservancy of Forests. In 1869 he retired from the Indian service, his labours on behalf of the improved system of forest management being officially acknowledged in complimentary terms. Returning to Scotland, Dr. Cleghorn temporarily filled the chair of Botany in Glasgow University during the indisposition of Professor Walker Arnott, and continued for many years to devote himself at Stravithie to his favourite botanical pursuits. He was a member of the Edinburgh Botanical Society, a Fellow of the Linnean Society and for several years President of the Royal Scottish Arboricultural Society.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination for the Fellowship at a meeting of the Board of Examiners on Wednesday, the 15th inst. :—

Baldwin, Aslett, L.R.C.P. Lond., M.R.C.S. Eng., Middlesex Hospital.
Curtis, Henry Jones, L.R.C.P. Lond., M.R.C.S. Eng., University College, London.
Hall, Charles Beauchamp, L.R.C.P. Lond., M.R.C.S. Eng., St. Mary's Hospital.
Hulke, Sydney Backhouse, L.R.C.P. Lond., M.R.C.S. Eng., Middlesex Hospital.
Keyser, Charles Ralph, St. George's Hospital.
Scrace, Frank Edward, L.R.C.P. Lond., M.R.C.S. Eng., University College, Bristol, and St. Bartholomew's Hospital.
Smith, Thomas Rudolph Hampden, L.R.C.P. Lond., M.R.C.S. Eng., Cambridge University and St. Bartholomew's Hospital.
Worth, Francis James, L.R.C.P. Lond., M.R.C.S. Eng., St. Mary's Hospital.

Twelve gentlemen were referred back to their professional studies for six months.

Passed on Thursday, the 16th inst. :—

Collard, Frederick Stuartson, L.R.C.P. Lond., M.R.C.S. Eng., St. George's Hospital.
Dyson, Malcolm Goodworth, St. Bartholomew's Hospital.
Fox, George Raymond, L.R.C.P. Lond., M.R.C.S. Eng., St. Bartholomew's Hospital.
Going, Robert Marshal, Trinity College, Dublin, and London Hospital.
Jaffrey, Francis, L.R.C.P. Lond., M.R.C.S. Eng., St. George's Hospital.
Lynch, Stephen Frederick, King's College, London.
Mundy, Herbert, St. Bartholomew's Hospital.
Ridley, Nicholas Charles, L.R.C.P. Lond., M.R.C.S. Eng., St. Mary's Hospital.
Spicer, Arthur Herbert, Guy's Hospital.
Sutcliffe, William Greenwood, L.R.C.P. Lond., M.R.C.S. Eng., St. Thomas's Hospital.
Wallace, Lewis Alexander Richard, L.R.C.P. Lond., M.R.C.S. Eng., Oxford University and St. Thomas's Hospital.
Walsh, John Henry Tull, Surgeon-Captain I.M.S., L.R.C.P. Lond., M.R.C.S. Eng., Westminster Hospital.

Eight gentlemen were referred back to their professional studies for six months.

Passed on Friday, the 17th inst. :—

Brown, Ralph Charles, M.B. Melb., Melbourne University and Westminster Hospital.
Caveragh-Mainwaring, Wentworth Rowland, M.B. Adelaide, Adelaide University and London Hospital.
Churchill, Joseph Henry, St. Bartholomew's Hospital.
Crowley, John Henry, M.B. Melb., M.R.C.S. Eng., Melbourne University.
Fromantle, Francis Edward, Oxford University and Guy's Hospital.
Novis, Thomas Shepherd, London Hospital.
O'Meara, Eugene John, Guy's Hospital.
Randall, Martin, M.R.C.S. Eng., L.R.C.P. Lond., University College, London.

Eight gentlemen were referred back to their professional studies for six months.

Passed on Monday, the 20th inst. :—

Evans, Evan, Guy's Hospital.
Wood, John Forrester, L.R.C.P. Lond., M.R.C.S. Eng., St. Bartholomew's Hospital.

Ten gentlemen were referred back to their professional studies for six months.

The following gentlemen having passed the necessary examination, and having conformed to the by-laws and regulations, have been admitted Members of the College :—

Adams, Percy Edward, L.R.C.P. Lond., St. Bartholomew's Hospital.
Bacon, Robert Alfred Edward, L.R.C.P. Lond., St. George's Hospital.

Barritt, John Thomas, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Basden, Harold Stevens, L.R.C.P. Lond., Cambridge University and London Hospital.
 Baxter, Stephen Edward, L.R.C.P. Lond., St. Thomas's Hospital.
 Bennett, Arthur George, L.R.C.P. Lond., St. Mary's Hospital.
 Birley, Hugh Kennedy, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Blackburn, Ernest Woodhead, L.R.C.P. Lond., Oxford University and St. Bartholomew's Hospital.
 Blackett, Edward Joseph, L.R.C.P. Lond., St. George's Hospital.
 Blount, George Bertie Clavell, L.R.C.P. Lond., St. Thomas's Hospital.
 Burnett, Frank Marsden, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Burrage, Henry Alfred, L.R.C.P. Lond., King's College, London.
 Burton, Leonard Launing, L.R.C.P. Lond., London Hospital.
 Butler, Thomas Harrison, L.R.C.P. Lond., Oxford University and St. Bartholomew's Hospital.
 Caldwell, Charles Holt, L.R.C.P. Lond., Mason College, Birmingham.
 Clark, William Gladstone, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
 Clemesha, William Wesley, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Conford, George James, L.R.C.P. Lond., Oxford University and St. Thomas's Hospital.
 Cooper, Robert Montague le Hunte, L.R.C.P. Lond., St. Mary's Hospital.
 Creneen, Sydney, L.R.C.P. Lond., Guy's Hospital.
 Crouch, Herbert Dhallice, L.R.C.P. Lond., St. Thomas's Hospital.
 Dalal, Katanah Dinsah, L.R.C.P. Lond., University of Bombay.
 Devereux, Norman, L.R.C.P. Lond., Mason College, Queen's and General Hospitals, Birmingham, and Middlesex Hospital.
 Dickin, Edward Percival, L.R.C.P. Lond., University of Edinburgh, Middlesex and St. Mary's Hospitals.
 Dixon, Walter Ernest, L.R.C.P. Lond., St. Thomas's Hospital.
 Dobbin, Edward John, L.R.C.P. Lond., Middlesex Hospital.
 Dodd, Frederick Lawson, L.R.C.P. Lond., Middlesex Hospital.
 Dodgson, Robert William, L.R.C.P. Lond., St. Mary's Hospital.
 Down, Edgar, L.R.C.P. Lond., London Hospital.
 Dunn, William Edward Nickolls, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Edge, Bruce Edgar, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Fison, Edmund Towers, L.R.C.P. Lond., University of Cambridge and St. George's Hospital.
 Fuller, Alfred Leonard, L.R.C.P. Lond., St. Thomas's Hospital.
 Gardner, William, L.R.C.P. Lond., St. Mary's Hospital.
 Gibbons, Arthur Philip, L.R.C.P. Lond., London Hospital.
 Gillies, Sinclair, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Goddard, Gerald Hamilton, L.R.C.P. Lond., University College, London.
 Griffiths, John Crisp, L.R.C.P. Lond., Mason College, Birmingham.
 Groves, Ernest William Hey, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Hallwright, Matthew Leslie Guy, L.R.C.P. Lond., Mason College, Queen's and General Hospital, Birmingham, and University College, London.
 Harrison, Herbert Meredith, L.R.C.P. Lond., St. Thomas's Hospital.
 Head, Ernest Edward, L.R.C.P. Lond., King's College Hospital.
 Heaton, Alan Baldwin, L.R.C.P. Lond., University of Cambridge, Yorkshire College, Leeds, and St. Thomas's Hospital.
 Higginson, George, L.R.C.P. Lond., University of Cambridge and London Hospital.
 Hopton, Ralph, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
 Horton, Walter Hartland, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Isaac, Matthew William Stuart, L.R.C.P. Lond., St. Bartholomew's Hospital.
 James, Charles Kemble, L.R.C.P. Lond., Middlesex Hospital.
 James, Frederick Charles, L.R.C.P. Lond., St. Thomas's Hospital.
 Jones, James Evan, L.R.C.P. Lond., St. Bartholomew's Hospital.
 King, Thomas Percy, L.R.C.P. Lond., Cambridge University and Guy's Hospital.
 Iano, John George Ogilby Hugh, L.R.C.P. Lond., Guy's and St. Thomas's Hospitals.
 Laslett, Maurice Howard, L.R.C.P. Lond., St. Thomas's Hospital.
 Lawson, Richard, L.R.C.P. Lond., St. Thomas's Hospital.
 Legg, Thomas Percy, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Lister, William Tindall, L.R.C.P. Lond., Cambridge University and University College, London.
 Lockett, George Vernon, L.R.C.P. Lond., University of Edinburgh.
 McArthur, Arthur Norman, L.R.C.P. Lond., University of Melbourne, King's College and Charing-cross Hospitals.
 Maide, Hubert Abraham, L.R.C.P. Lond., Charing-cross Hospital.
 Marks, Herbert William James, L.R.C.P. Lond., Cambridge University and St. George's Hospital.
 Marriott, Arthur, L.R.C.P. Lond., Firth College, Sheffield, and University College Hospital.
 Meacher, John Howard, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Mills, Henry William, L.R.C.P. Lond., University of Edinburgh and St. Thomas's Hospital.
 Moffat, Henry Alfred, L.R.C.P. Lond., Guy's Hospital.
 Montgomery-Smith, Edwin Charles, L.R.C.P. Lond., London Hospital.
 Moore, Percy Lyndon, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
 Mott, Clarence Harry, L.R.C.P. Lond., London Hospital.
 Mumford, Wilfred George, L.R.C.P. Lond., Guy's Hospital.
 Norbury, William, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
 Ogden, Ogden Watson, L.R.C.P. Lond., Durham University.
 Owen, Arthur Dudley, L.R.C.P. Lond., Royal Infirmary, Bristol.
 Owles, Oscar William, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Pakes, Walter Charles, L.R.C.P. Lond., Guy's Hospital.
 Palin, Edward Watson, L.R.C.P. Lond., Oxford University and St. Thomas's Hospital.

Pardoe, John George, L.R.C.P. Lond., Aberdeen University and Charing-cross Hospital.
 Peake, William Harland, L.R.C.P. Lond., Royal Infirmary, Newcastle, and Guy's Hospital.
 Pearson, Maurice Grey, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Perry, Edgar Courtney, L.R.C.P. Lond., St. Thomas's Hospital.
 Perry, Edmund Ludlow, L.R.C.P. Lond., St. Thomas's Hospital.
 Phillips, David, L.R.C.P. Lond., Middlesex Hospital.
 Pinchard, Michael Biddulph, L.R.C.P. Lond., Middlesex Hospital.
 Pitt, William Carey, L.R.C.P. Lond., Guy's Hospital.
 Playfair, Ernest, L.R.C.P. Lond., King's College Hospital.
 Price, George Basil, L.R.C.P. Lond., University College Hospital.
 Reynolds, Frank Ernest, L.R.C.P. Lond., London Hospital.
 Richards, John, L.R.C.P. Lond., University College Hospital.
 Rigg, Samuel Edward, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Sedgwick, Hubert Redmayne, L.R.C.P. Lond., Cambridge University, London, and St. Thomas's Hospital.
 Smith, Frank Loughton, L.R.C.P. Lond., Mason College, Queen's, and General Hospital, Birmingham.
 Smith, Lewis Albert, L.R.C.P. Lond., London Hospital.
 Smith, Percy Montague, L.R.C.P. Lond., St. Mary's Hospital.
 Sowry, George Herbert, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Stanley, Hubert, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
 Statham, Charles John Baron, L.R.C.P. Lond., Bombay University and Guy's Hospital.
 Stephenson, John Stuart, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Stewart, Charles Balfour, L.R.C.P. Lond., Cambridge University and Royal Infirmary, Liverpool.
 Stokes, John Wilfred, L.R.C.P. Lond., University College Hospital.
 Swainson, Edwin Arthur Cleveland, L.R.C.P. Lond., Cambridge University and Middlesex Hospital.
 Thomas, William Protheroe, L.R.C.P. Lond., London Hospital.
 Thompson, Henry Evans, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Townend, Richard Hamilton, L.R.C.P. Lond., London Hospital.
 Toye, Edwin Josiah, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Tresidder, Percy Edgar, L.R.C.P. Lond., Guy's Hospital.
 Tribe, Paul Cunningham Edward, L.R.C.P. Lond., King's College Hospital.
 Tucker, Ernest Frederick Gordon, L.R.C.P. Lond., London Hospital.
 Van Someren, Ernest Herbert, L.R.C.P. Lond., Guy's Hospital.
 Vivian, John Henry Percival, L.R.C.P. Lond., St. Thomas's Hospital.
 Walker, Henry Roe, L.R.C.P. Lond., King's College Hospital.
 Walls, Edward Geoffrey, L.R.C.P. Lond., Mason College, Queen's, and General Hospital, Birmingham.
 Wanhill, Charles Frederick, L.R.C.P. Lond., University College Hospital.
 Waring, Anthony Henry, L.R.C.P. Lond., University College Hospital.
 Warrington, Richard James, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
 Waters, Fred William, L.R.C.P. Lond., St. Thomas's Hospital.
 Webster, Thomas Leeming, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester, and St. Bartholomew's Hospital.
 Whitley, Henry Walter, L.R.C.P. Lond., Charing-cross Hospital.
 Wilkins, John Claude Verity, L.R.C.P. Lond., Guy's Hospital.
 Wilks, Morris, L.R.C.P. Lond., University College Hospital.
 Williams, David Franklin, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool.
 Williams, Kenway Thomas, L.R.C.P. Lond., Mason College, Queen's and General Hospital, Birmingham.
 Williams, Leonard Addams, L.R.C.P. Lond., Middlesex Hospital.
 Willis, William Morley, L.R.C.P. Lond., University College and Royal Infirmary, Bristol.
 Winter, John Bradbury, L.R.C.P. Lond., Guy's Hospital.
 Wiseman, David William, L.R.C.P. Lond., Charing-cross Hospital.
 Woodward, Arthur, L.R.C.P. Lond., St. Bartholomew's Hospital.
 Worthington, George Vigers, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
 Wyborn, Walter Edward, L.R.C.P. Lond., Charing-cross Hospital.
 Young, Archibald, L.R.C.P. Lond., Firth College, Sheffield, and University College Hospital.
 Young, Charles Whitwick, L.R.C.P. Lond., Charing-cross Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the under-mentioned subjects:

Surgery.—J. Ash, St. Thomas's Hospital; E. R. Bowen, Brooklyn and Bristol; E. B. Cornaby, Cambridge and London Hospital; A. H. P. Dawney, University College and St. Thomas's Hospital; R. A. Fegan, St. Bartholomew's Hospital; C. F. Le Sage, London Hospital; E. D. Macnamara, Westminster Hospital; A. P. Murtz, King's College; G. H. Smith, St. Bartholomew's Hospital; H. Williams, Middlesex Hospital.
Medicine, Forensic Medicine, and Midwifery.—S. B. Blomfield, Westminster Hospital; W. E. Kirby, University College; W. G. Noble, London Hospital.
Medicine and Midwifery.—A. J. Petyt, Cambridge and Leeds; M. White, St. Thomas's Hospital.
Medicine.—A. C. Fenn, St. Bartholomew's Hospital; W. A. Higgins, Cambridge and Birmingham; M. Umanaki, Kharcoff.
Forensic Medicine and Midwifery.—A. H. P. Dawney, University College and St. Thomas's Hospital; B. L. Dhingra, Lahore; P. G. Lodge, Leeds and St. Thomas's Hospital.
Forensic Medicine.—E. D. Macnamara, Westminster Hospital; G. H. Smith, St. Bartholomew's Hospital.
Midwifery.—W. B. Bremner, King's College; H. Clapham, Sheffield; J. H. R. Pigeon, Bristol; W. H. Reed, Bombay and King's College; A. Robinson, Leeds; E. H. Tipper, Guy's Hospital; L. G. W. Tyndall, St. Mary's Hospital.
 To Messrs. Bremner, Fenn, Higgins, Kirby, Le Sage, Macnamara, Noble, Petyt, and Umanaki was granted the diploma of the society.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. Kayserling has been appointed Assistant in the Pathological Institute and Dr. René du Bois-Reymond, a son of the eminent physiologist, Assistant in the Experimental Department of the Physiological Institute. Dr. Günther has been appointed to succeed Dr. Thierfelder as Custos of the Museum of Hygiene. *Bordeaux*: Dr. Boursier has been appointed to the Professorship of Clinical Gynaecology. *Chicago (Medical College)*: Dr. W. S. Hall has been appointed Professor of Physiology. *Cracow*: Dr. Alexander Rosner has been recognised as *privat-docent* in Midwifery and Gynaecology. *Prague (German University)*: Dr. Wunscheim has been recognised as *privat-docent* in Pathological Anatomy. *(Bohemian University)*: Dr. Karl Chodonusky has been promoted to the Extraordinary Professorship of Pharmacology. *Vienno*: The Minister of Education has appointed Dr. Norbert Ortner *privat-docent* in Internal Medicine and Dr. Leopold Réthi as *privat-docent* in Laryngology and Rhinology.

PRESENTATIONS.—Dr. Herbert Bramwell of Cullercoats, Northumberland, on the occasion of his leaving the district, has been presented with a handsome silver tea service and an album containing local views, with an address bearing the names of the subscribers, as a token of esteem and regard from friends in North Shields, Tynemouth, Cullercoats, Whitley, and Monkseaton. — Dr. Edmund Downes of Eastbourne has been the recipient of a testimonial, consisting of a handsome electro-plated tea kettle and stand and a hot-water jug, from the members of the Eastbourne Ambulance Class, in recognition of his generous services as honorary instructor of the class for some years. — On the 18th inst. Mr. W. Davies, M.R.C.S. Eng., of Peckham, was presented with a handsome timepiece, aneroid barometer, thermometer, and perpetual calendar, all combined in one piece. The presentation was made on behalf of the Ambulance Class for Women lately conducted by him at Messrs. Braby's Works, Deptford.

EDINBURGH ROYAL INFIRMARY RESIDENTS CLUB.—The inaugural dinner of this club was held in the Royal Hotel, Edinburgh, on May 3rd. No less than seventy-six members were present, many of them having travelled long distances. Dr. Alexander James occupied the chair, and proposed the toast of the evening, "The Residency," in a speech containing many interesting reminiscences of the old infirmary. Sir Thomas Grainger Stewart gave "The Chairman," and afterwards replied to the toast of the "Senior Old Resident Present," which was proposed by Dr. C. E. Douglas. The proceedings terminated with a symposium, which was no less successful than the dinner. At a business meeting of the club held before the dinner the following were elected office-bearers for the year:—President, Dr. Alexander James. Secretary: Dr. Claude B. Ker. Treasurer: Dr. R. J. A. Berry. Committee: Drs. F. M. Caird, G. A. Gibson, C. C. Easterbrook, Cattinach, Dowden, and Musgrove. The club now numbers more than 170 members and seems certain of a prosperous future.

LITERARY INTELLIGENCE.—We have received the first volume of "Dennis's System of Surgery," which promises to be a very full and authoritative representation of the state of surgery in the United States. It is edited by Frederick S. Dennis, M.D., Professor of Surgery in Bellevue Hospital Medical College, who is also a Member of the Royal College of Surgeons of England. He is assisted in the editorship by John S. Billings, M.D., LL.D. Edin., D.C.L. Oxon., and Deputy-Surgeon-General of the United States. The articles in this volume alone include one by Dr. Billings on the History and Literature of Surgery; one on General Bacteriology of Surgical Infections by Wm. H. Welch, M.D., Professor of Pathology of the Johns Hopkins University; one on Surgical Pathology, including Inflammation and the Repair of Wounds, by William T. Councilman, Professor of Pathology, Harvard Medical School, Boston; one on Fractures and Dislocations, by Professor Dennis; one on Anæsthesia by Horatio Wood, M.D., Professor of Materia Medica and Therapeutics, University of Pennsylvania; and several other articles of first-rate importance as expositions of the present state of American knowledge and doctrine. We must defer any detailed criticisms of this work, but we hasten to announce its appearance as a fact of credit to American medical literature and to congratulate Professor Dennis on such a body of colleagues.

The Glasgow University Club, London, will dine in the Holborn Restaurant on Monday next, May 27th, at 7.30 P.M. The Right Hon. Henry Campbell-Bannerman, M.P., Secretary of State for War, will preside, and the guests of the club will be General Sir Evelyn Wood, V.C., G.C.B., and Mr. J. Fletcher Moulton, Q.C., M.P. Graduates or former students of Glasgow University who have not yet joined the club and who may be desirous of doing so are requested to communicate with either of the hon. secretaries, Mr. Norman M. Maclehose, 13, Queen Anne-street, Cavendish-square, W., or Mr. James M. Dodds, Dover House, Whitehall, S.W.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—"The Experience of the Hospital in Abdominal Surgery (gynaecological operations apart) during the years 1888-1894 inclusive" will form the subject of three lectures which will be delivered by Mr. T. Holmes, F.R.C.S. (the Hunterian Lecturer in Surgery) on June 5th, 6th, and 12th, at 5 P.M. Dr. W. Howship Dickinson (the Baillie Lecturer in Physic), will also deliver the following lectures:—June 19th, at 5 P.M., on Some recent observations relating to the Cardio-vascular Change of Renal Disease; June 26th, at 5 P.M., on Some points touching Disease of the Heart; and July 3rd, at 5 P.M., on Dropsy. All the lectures will be delivered in the school. Members of the profession will be admitted on presenting their visiting cards.

DERMATOLOGICAL SOCIETY OF LONDON.—The annual meeting of this society, founded in 1882, was held on May 8th, and important changes in the constitution of the society were unanimously adopted. Previously the number of members was limited to thirty for the more convenient examination of patients, but it was resolved that henceforth there should not be any limit to the number. The following gentlemen were elected to form an Executive Council for the session 1895-96:—Mr. William Anderson, Dr. Cavafy, Dr. Radcliffe Crocker, Dr. James Galloway, Dr. Robert Living, Mr. Malcolm Morris, Dr. J. F. Payne, Dr. E. C. Perry, Mr. Marmaduke Sheld, Dr. Frederick Taylor; Dr. Stephen Mackenzie (Treasurer); Dr. T. Colcott Fox and Dr. J. J. Pringle (Hon. Secs.).

BEQUESTS AND DONATIONS.—The late Deputy Inspector of Hospitals, Dr. G. Willes, R.N., has bequeathed £500 each to the Royal Portsmouth Hospital and the Portsmouth Eye and Ear Infirmary. — Mrs. Anne Groom, widow of the late Mr. William Groom, of West Derby, has bequeathed £100 each to the Liverpool Hospital for Cancer and Skin Diseases, the Liverpool Infirmary for Children, and the Home for Female Incurables at Liverpool, and £400 to the Liverpool Medical Missionary Society. — Sir James Reckitts has given £1000 towards forming an endowment fund for the Withernsea Convalescent Home. — The London Clothworkers' Company has granted donations of £70 to the North-Eastern Hospital for Children, Hackney-road, Shoreditch, and of 80 guineas to Queen Charlotte's Lying-in Hospital, Marylebone-road. — Mr. Frederick Wilder of Hurley Hall, Berkshire, has contributed £100 towards the cost of the proposed new operating theatre at the Royal Berkshire Hospital, Reading. — The Treasurer of the Metropolitan Hospital, Kingsland-road, has received from the Shoreditch Concert Committee £104 3s. 1d., the proceeds of a concert held in the town-hall, Shoreditch. — Mrs. Emma Mackenzie, late of Kensington Park-gardens, has bequeathed £1000 to the Hospital for Incurables, West Hill, Putney. — The late Mr. Thomas W. Thompson of Amptill-square, Hampstead-road, has bequeathed £100 each to the University College Hospital, Gower-street, London, and the Hospital for Incurables, Putney. — Mrs. Sarah R. Smyth, late of Stevenage, Herts, has bequeathed £300 to the Herts Convalescent Home, St. Leonards. — The following contributions have been made by the London City Companies to the special fund now being raised for St. Thomas's Hospital: the Merchant Taylors' Company, 500 guineas; the Armourers' and Braziers' Company, 100 guineas; the Goldsmiths' Company, £500; the Vintners' Company, £52 10s.; the Dyers' Company, £25; the Ironmongers' Company, 100 guineas; and the Waxchandlers' Company, 25 guineas. To the same fund the London and South-Western Railway Company has contributed £105 and Lord Iveagh £1000. — The late Earl of Moray has bequeathed £50,000 to the Edinburgh Royal Infirmary. — Alderman Bindloss, late Mayor of Kendal, has bequeathed £1000 each to the Middlesex Hospital, the St. George's Hospital, and King's College Hospital, London.

At the opening of the St. Mary's Hospital bazaar at Portman Rooms on June 27th by the Princess of Wales she will be conducted through the bazaar by the Duke of York as President of the Hospital.

ROYAL MICROSCOPICAL SOCIETY.—May 15th, the President, Mr. A. D. Michael, in the chair. Mr. J. Swift exhibited an improved form of the Nelson Microscope Lamp fitted with mechanical movements, and also a "Wales" microscope which had been fitted with the new mechanical stage.—Mr. T. Comber read a paper on the "Development of the young valve of *Trachyneis Aspera*." The subject was illustrated with lantern photographs exhibited upon the screen.—Miss Ethel Sargent's paper on the "First Nuclear Division in the pollen mother cells of *Lilium Martagon* &c.," was communicated by Dr. D. H. Scott. A discussion ensued in which Professor J. B. Farmer, Mr. Spencer Moore, and Dr. Scott took part.

MEDICAL SOCIETY OF LONDON.—The following officers were elected to serve during the coming seasonal year:—President: Sir James Crichton Browne, M.D., F.R.S. Vice-presidents: Sidney Coupland, M.D., Henry H. Clutton, John C. Thorowgood, M.D., and Charles B. Lockwood. Librarian: William Henry Allchin, M.D. Honorary Secretaries: Amand Routh, M.D., and George R. Turner. Honorary Secretary for Foreign Correspondence: Heinrich Port, M.D. Council: Howard Barrett, J. Mitchell Bruce, M.D., John Cahill, Andrew Clark, Sir William B. Dalby, F. Swinford Edwards, David Ferrier, M.D., F.R.S., Archibald E. Garrod, M.D., F. de Havilland Hall, M.D., Norman Kerr, M.D., Edward D. Mapother, M.D., H. Montague Murray, M.D., Edward J. Nix, M.D., James W. J. Oswald, M.D., William Pasteur, M.D., Charles H. Ralfe, M.D., Frederick T. Roberts, M.D., Frederick Treves, John Tweedy, and Joseph White.

THE FIFTH INTERNATIONAL CONGRESS OF OTOTOLOGY.—The above meeting will be held in Florence, under the presidency of Professor Grazi, from Sept. 23rd to 26th next. The following are the subjects selected for discussion:—1. The Treatment of Intracranial Abscesses consequent on Purulent Diseases of the Ear, introduced by Dr. Thomas Barr of Glasgow. 2. General Treatment in Diseases of the Ear, introduced by Dr. Gallé of Paris. 3. General Treatment in Diseases of the Internal Ear, introduced by Professor Gradilugo of Turin. 4. The Present State of our Knowledge of the Pathology of the Labyrinth, introduced by Professor Politzer of Vienna. 5. On the Physiology of the Middle Ear, introduced by Dr. Charles Secchi of Bologna. All members of the profession who intend to contribute papers or to be present at the congress are requested to communicate with the secretary not later than June 15th. Early in July each intending *congressista* will receive a detailed programme of the meeting. The official languages are Italian, French, German, and English. The subscription, which includes a copy of the printed transactions of the congress, is twenty francs. The secretary-treasurer is Dr. T. Bobone, San Remo.

The annual general meeting of the Society for the Relief of Widows and Orphans of Medical Men was held on Thursday, May 16th, at 5.30 p.m. The president (Sir James Paget) presided. From the report read by the secretary it appeared that 13 new members had been elected during the year, 11 had died, and 4 resigned, leaving 306 on the books. Two widows had been admitted, 3 had died, the number on the books at the end of the year being 53. The number of orphans remained the same as in 1893—viz., 9. The grants during the year amounted to £2805, including a Christmas present of £303. The expenses were £241. The receipts available for the payment of grants and expenses had been £3262 and the expenditure £3046. A sum of £785 had been invested. Sir J. Russell Reynolds and Mr. Willett were elected vice-presidents, and Dr. Buzzard, Dr. Pollock, Mr. Manley Sims, Dr. Kempe, Mr. Underwood, Mr. Pearce Gould, and Dr. Lewers were elected directors to fill the vacancies caused by death and retirement. A grant of £26 was made under by-law 78. A vote of thanks, proposed by Mr. Christopher Heath, to the editors of the medical journals for their assistance in making known the work of the society, was passed unanimously. The proceedings terminated with a vote of thanks, proposed by Dr. Glover, to Sir James Paget, the president, for his kindness in taking the chair at the meeting.

NORTH-WEST LONDON CLINICAL SOCIETY.—A clinical meeting of this society was held on May 8th. Dr. R. H. Milson in the chair.—Dr. Harry Campbell showed a case of Post-hemiplegic Hemichorea in a woman. The condition dated from infancy, and Dr. Campbell thought in all such cases the cause was softening rather than hemorrhage. He had given bromides and opium with benefit.—Dr. Guthrie showed a case of Violent Post-hemiplegic Spasms in a man aged twenty-five. The symptoms pointed to implication of the cortical motor area, and Dr. Guthrie raised the question of operation by trephining.—Mr. Jackson Clarke showed a child with a Syphilitic Skin Lesion of the Buttock, and exhibited specimens of Gummata removed from the Viscera of other patients. He advocated treatment by mercurial inunction in infantile syphilis. Dr. Coode Adams regarded the lesion as tuberculous, and based this view on the family history.—Mr. Gordon Brodie showed a large Angioma of the Buttock. He proposed to remove it after preliminary electrolysis.—Mr. Brodie also showed a case of Dermatitis attributed to contact with bichromate of potash.—Dr. Herschell, Dr. Coode Adams, and Dr. Gill spoke.—Dr. Harry Campbell showed the heart and spleen from a case of Ulcerative Endocarditis.—Dr. Cameron, Mr. Clayton, and Dr. Guthrie joined in the discussion.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Inebriates.

THE Lord Chancellor has introduced into the House of Lords a Bill to amend the Inebriates Acts of 1879 and 1885 and the law respecting drunkenness.

Opium Commission.

There has been published, by way of supplement to the report of the Royal Commission on Opium, a note by the Maharaja Bahadur of Durbhanga. The Maharaja in this note states that the report of the Commission is, on the whole, drawn up in accordance with the spirit of the resolutions that were passed at the last sitting in Bombay, and as such he is prepared to accord a general support to it. He wishes, however, to lay before the British public the views entertained on the opium question by the majority of the Indian thinking public. This he does in the note.

Cock-fighting in Scotland.

There has been passed through the two Houses of Parliament to put county authorities in Scotland in a position to deal with cock-fighting, an ancient and brutal form of sport, which appears to have had a somewhat extensive revival in certain parts of Scotland.

Factories and Workshops Bill.

The Grand Committee continues to make substantial progress with the Factories and Workshops Bill. At its recent meetings it has been mainly engaged with the provisions as to the cleaning and protection of machinery and the precautions against fire. On Tuesday, May 21st, some time was spent with Clause 11, which provides for the representation of workmen on arbitrations as to special rules applicable to certain dangerous trades. These rules at present are drawn up by the Home Office, and the employer can demand an arbitration but not the workman, and the object of the clause is to bring in the latter. Mr. John Burns took up the position that there should be no arbitration at all and that the matter should be left in the hands of the Home Office. His idea was that the clause gives employers and workmen the power to contract out of healthy and sanitary conditions of work. Mr. Asquith thought that both employers and workmen would hesitate before handing over this great power to a Government department. The result of the debate was to leave the clause untouched in this respect.

HOUSE OF LORDS.

THURSDAY, MAY 16TH.

Richmond Lunatic Asylum, Dublin.

Lord Riddlesdale said, in reply to a question put by the Earl of Belmore, that the estimated cost of remodelling this asylum was £60,000. For that sum suitable buildings and accommodation would be provided for the residue of the lunatics of the district (about 300 in number) who could not be accommodated in the new buildings at Portrane. The new buildings were estimated to cost £240,000 and to accommodate 1200 lunatics. The Irish Government at first held the opinion that it would be better to abandon the existing asylum and erect new buildings on a better site, and they made representations to that effect to the Board of Control; but the answer was that whereas the old buildings were worth £100,000 while used for the accommodation of lunatics, they would not be worth more than £20,000 if sold in the open market. After that answer the Irish Government did not feel justified in further interference with the discretion of the Board of Control.

Lord Ashbourne, in the course of a short speech, expressed strong objection to this large sum of money being spent on a bad and condemned site, and said that the better plan would be to seek a new site with healthy surroundings, and there erect an asylum in accordance with the requirements and suggestions of modern science for the treatment of the insane.

HOUSE OF COMMONS.

THURSDAY, MAY 16TH.

The Tuberculosis Commission.

Mr. Shaw-Lefevre said, with regard to this subject, that the Commission made no recommendations. It had arrived at various conclusions of fact as to the existence of tuberculosis in animals and as to the possibility of its being communicated to consumers of meat and milk. These conclusions appeared to point to the expediency of an extension of the system of inspection of dairies, slaughter-houses, and butchers' shops, and possibly to the general establishment of public slaughter-houses. Until the evidence taken by the Commission was published and time had been given for the consideration of the very large and difficult questions involved he should be quite unable to state what the intentions of the Government were upon these matters, or whether it was desirable to have a further inquiry as had been suggested.

FRIDAY, MAY 17TH.

Insanitary Workshops in Glasgow.

Mr. Schwann asked the Home Secretary how many complaints had been made by the factory inspectors in Glasgow to the local sanitary authorities in that city with reference to defects and insanitary conditions in workshops during the month of April last, and how many of them could have been rectified immediately by the factory inspectors had they possessed the same power to deal with defective sanitation in workshops that they possess in factories.

Mr. Asquith replied that thirty-eight complaints were made to the sanitary authorities in Glasgow in April, including twenty-two workshops in an uncleanly state, five workshops overcrowded, six workshops requiring additional waterclosets or waterclosets requiring structural alteration. Of these, twenty-six could have received attention by Her Majesty's inspectors of factories had they the same power in workshops as they have in factories.

MONDAY, MAY 20TH.

Sanitary Inspectors in Scotland and Private Practice.

Sir George Trevelyan informed the House that sanitary inspectors are engaged in private business or hold other public appointments in the following Scottish counties—viz., Aberdeenshire, Fife, Nairn, Peebles, Selkirk, and Orkney and Zetland.

The Veterinary Department.

Mr. Herbert Gardner, President of the Board of Agriculture, replying to a question, said that on the rearrangement of business which took place on the retirement of Professor Brown in 1893, the term "Animals Department" was applied to the officers engaged on duties which were connected with the animal industry, and which did not require the possession of veterinary knowledge for their proper performance. The term "veterinary" would have been inappropriate to the division thus constituted, and a separate status was, moreover, assigned to the veterinary staff. The principal of the division was Major John Trencutt Tennant, who was not a veterinary surgeon, but who had had nearly twenty years' experience of the business upon which he was engaged, and to whose ability and work in the past agriculturists were very greatly indebted. He was aware that many members of the veterinary profession would have preferred that no changes in their organisation should have been made; but he was satisfied that those changes were necessary in the interest of the public service, and he did not propose—nor, indeed, was it in his power—to make any other arrangements.

TUESDAY, MAY 21ST.

Influenza.

Mr. Percy Thornton asked whether the promised inquiry into the different nature of ordinary cold and the malarial epidemic termed influenza, which had visited England each winter since 1889 and occasionally appeared in the summer also, would include all available data concerning the sequelæ or after-effects of the complaint in its later phases.—Sir Walter Foster replied that the object of the inquiry was to ascertain whether any relations existed between the ordinary influenza cold and the malarial epidemic influenza, and it had been found that the acute stages of the two diseases alone afforded an opportunity for the necessary bacteriological investigation. It was not considered that any further study of the sequelæ of the two diseases was necessary.—Mr. Thornton asked whether medical men would be encouraged to give their experience to the Medical Department of the Local Government Board.—Sir Walter Foster said he felt sure that medical men required no encouragement to submit anything for the benefit of the public in stamping out this serious disease.

The Dangers of Electric Lighting.

Mr. Bryce, President of the Board of Trade, replying to Mr. Weir, said that private electric lighting companies having statutory powers were under obligations similar to those imposed on local authorities, and were also prohibited from using overhead wires without the consent of the Board of Trade and the local authority. Private electric lighting companies not having statutory powers were subject to the regulations for the protection of the public safety prescribed under the provisions of the Electric Lighting Acts, 1882 and 1888, although the use of overhead conductors was not prohibited by those Acts. Moreover, urban authorities under the Public Health Act of 1890 were empowered to make regulations for the prevention of danger or obstruction to the public from wires stretched over, along, or across any street.

WEDNESDAY, MAY 22ND.

Insurance of Children.

On the motion of Sir Richard Webster, the Funeral Expenses of Children Insurance Bill was read a second time.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on Food Products Adulteration resumed the examination of witnesses on Tuesday, May 21st, Sir Walter Foster occupying the chair.

Mr. F. G. Ivey, of Messrs. Hansen, Son, and Barter, London, who attended the Committee on the suggestion of the London Chamber of Commerce, said in reply to the Chairman, that he was not in favour of any great alteration in the law with regard to coffee and chicory mixtures. He thought that where the proportion of coffee was in excess of that of chicory, the article should be called coffee and chicory, and where the proportion of chicory was in excess of coffee it should be called chicory and coffee. He would not put the proportions on the labels. So for analysts had not been able to arrive at the proportions of the two articles found in the mixtures, and while that was so he did not think it right to state proportions on the labels. In his view the public did not require to know the proportions, because they bought according to the price and were well aware when they offered a low figure that they were getting a large proportion of chicory.—If the only security the public has is the price then a great deal of what has been done under the Adulteration Acts is useless because the public can protect themselves?—Yes, but the public are alive to their own interests.—The argument against all this legislation was that the purchaser might take care of himself, but the State determined otherwise, and said we will try to take care of the purchaser. Do you wish to go back to the old platform?—I would stand upon the present platform and not depart from it. In 1882 it was proposed in Parliament that the proportions should be stated on the label, but the proposal was rejected. The view he took was that the difficulties of analysts were so great that any attempt to specify on the label the exact proportions of chicory and coffee would lead to unjust prosecutions. He would certainly modify this view if he found the difficulties of analysts were not so great as he believed them to be. The sale of coffee had not increased in recent years, and this he attributed to the very low price of tea and the fact that the English people were not a coffee-drinking people. He had not the slightest doubt that if Parliament interfered with the sale of mixtures the consumption of coffee would still further fall. In very many districts the sale of mixtures was far in excess of pure coffee; in the case of some districts it represented as much as 90 per cent. of the trade. Best coffee cost the grocer about 1s. 4d. per lb., and the chicory he would mix with it about 3d. per lb.

By Mr. Jeffreys: He would have no further restriction put upon the trade in mixtures, because the trade was honestly conducted and the public were satisfied. He could not admit for a moment that the public were deceived. If a customer asked for pure coffee and was supplied with a mixture then the vendor would be liable to prosecution under the present law.

By Mr. Kilbride: He did not think that grocers made undue profit by the sale of mixtures, because if the customer found he was supplied with an inferior article he would transfer his custom elsewhere.

Mr. J. C. Sanderson, honorary secretary of the Coffee Association of London, stated that in 1886 he had forty-three samples of mixtures taken in different parts of London analysed, with the result that they were found to contain on an average 50 per cent. of chicory, burnt sugar and other vegetable substances. Twenty-two of the samples were labeled French coffee, and contained from 62 to 93 per cent. of chicory, the average being 70 per cent. These mixtures were sold at prices which represented something like 100 per cent. profit to the vendors. He had no reason to believe that the state of things had improved since 1886. He thought that the proportions of chicory and coffee should in the interests of the public be stated on the label, and he felt confident that if makers were compelled to do this they would adopt better methods of manufacture to enable them to state the proportions. As things were at present, he had not heard analysts say much about difficulty experienced by them in determining the proportions. He considered the law insufficient. He considered that at the present moment makers had a licence to mix as much chicory as they liked with coffee, so long as they put on a notice saying that the article was sold as a mixture of chicory and coffee. This trading with the name of coffee should not be allowed. When there was a greater proportion of chicory than coffee present they should call the article "chicorino" or something of that sort, or they should make people sell coffee and chicory separately, and allow the purchaser to mix them.

Mr. Innes Rogers, of Messrs. Joseph Travers and Son, Limited, London, said he had been requested to give evidence as to the general grocery trade by the London Chamber of Commerce. He was strongly opposed to the unlimited use of chicory in the making of coffee mixtures. In his opinion, coffee was taken because of the vegetable alkaloids, which afforded a stimulus to the nerves, and if they substituted a roasted vegetable root like chicory, which had none of these alkaloids, they interfered with what the public desired. He considered that the present use of chicory was an abuse of the privilege given by Parliament, and therefore he thought the privilege should be modified or limited in some way. If people did not get the stimulus they expected from the coffee or coffee mixture they resorted to something else, probably tea, and in this way the consumption of coffee suffered. As a matter of fact, the present coffee trade was not a trade in coffee but a trade in chicory. He would have the proportions stated in the same way as the strength of spirits was stated, and if this were done the public would be protected and the trade would not suffer. He would enforce a limit beyond which chicory might not be used. Discussing the Act of 1875 generally, witness said it was well meant, but it was no deterrent to crime, not being sufficiently stringent and far-reaching. So far as the spice trade was concerned, there had been more adulteration since than before the Act. A good many years ago THE LANCET made an inquiry as to the state of the food-supply throughout London, and their commissioners found an extraordinary amount of adulteration. But in the old days, before THE LANCET inquiry, the people who did the adulteration worked upon a small scale and with little scientific knowledge; nowadays they worked on a great scale and called in the aid of science. It had become a case of setting science to catch science. Witness then explained to the Committee different methods by which pepper and ginger were adulterated. In this connexion he advocated that prosecutions should be directed against the manufacturer, the wholesale dealer, and the importer, as

well as against the retailer, who very often was in no way to blame for the nature of the article he sold.

The examination of Mr. Rogers was not concluded when the Committee adjourned.

The Committee met again on the following day, with Sir Walter Foster in the chair.

Mr. Innes Rogers was further examined by members of the Committee. He expressed the opinion that there was a considerable amount of direct adulteration in the grocery trade, affecting such articles as spices, arrowroot, seeds, and liquorice. The London Chamber of Commerce had passed a number of resolutions on the subject. They had declared, among other things, that the operation of the Adulteration Acts should be extended to wholesale dealers, that food should be held to include all articles used in the preparation of foods and drinks, that the Government should be called upon to establish a central and fully equipped analytical department, that the Government should have power to determine, fix, and vary, with reasonable notice, standards of purity, and that travelling inspectors should be appointed to see to the enforcement of the law. His opinion was that direct adulteration was not properly dealt with under the existing law. Very often there was no prosecution until a great deal of mischief had been done, and then the small retailer would be dealt with, although he had not committed the adulteration and probably knew nothing of it; while the wholesale manufacturer, who really committed the fraud and profited by it, was left unpunished. Even in cases where the wholesale manufacturer was reached the penalties were insufficient as deterrents. He would have the whole stock seized and imprisonment or heavy fines imposed. He did not wish to cast any reflection on the inspectors, but they went where they could most easily obtain a conviction, and he had no doubt that they purposely selected the green assistant. He was aware that in many places the inspectors did not make the purchases themselves, but employed other persons for the purpose. In the case of mixtures of coffee and chicory, the makers as a rule gave the retailers full warning that the article they supplied was not pure coffee. In his opinion the administration of the present adulteration laws was in the last degree capricious and unsatisfactory. In some districts there were no prosecutions at all, and in some he had reason to believe there was actual connivance between the petty officers of the law and the offenders. In some districts the local authorities found the expense of exposing adulteration too great for them to undertake it. The analysts as a body were entitled to the greatest respect. With the imperfect means at their disposal they had done wonders. But at the same time appointments had been made of totally unfit men. Medical men and pharmaceutical chemists had been appointed who had no knowledge of the subject, and, moreover, the salaries paid were quite insufficient. There was no general supervision of analysts, and analysts received no aid from the Government in pursuing their work. Although he himself had nothing to complain of in connexion with the Somerset House laboratory, it was frequently said that it was behind the times. He would bring all the Acts dealing with adulteration into one Act, which might be called the Adulteration Act, and he would have all places where food, drugs, or drink were sold open to inspection at all reasonable hours.

Mr. J. C. Foster, member of a firm of spice merchants in Great Tower-street, London, gave evidence as to adulteration carried on in liquorice, arrowroot, caraway, pepper, and ginger. Liquorice, he said, was adulterated to the extent of 50 per cent. of foreign substances. Flour and miller's sweepings were used, with the result that after a time the liquorice root decayed and became infested with weevils. The view he took was that nothing that contained less than 95 per cent. of liquorice should be allowed to be called liquorice. Arrowroot was adulterated with farino and potato starch, this adulteration being largely practised in England. Pepper was adulterated with ground rice, long pepper, olive stones, &c.

Mr. D. R. Harvest, of Thames-street, London, a gentleman who has been engaged in the spice and grocery trade for fifty years, expressed the opinion that the Food and Drugs Act had proved very beneficial in the case of ground pepper and ground ginger. The adulteration of these articles used to be largely carried on by wholesale firms, but the Act checked it, and he might say that it had received its death-blow from the vigorous application of the law in various parts of England. Not very long ago a consignment of white pepper was received from the Straits Settlement. Experts were led to believe that it was the pure article, but subsequently it was found to consist almost entirely of small clay pellets exactly resembling in shape and colour the genuine article. The fraud was said to have been practised on the importers by the Chinese before shipment. The greater part of the candied peel sold was pure, but some few makers had introduced a cheaper article, known to the initiated as candied skins—that was lemon and other kinds of peel from which the essences had been extracted. In his opinion the sale of baking powder mixed with alum should be treated as an offence against the Act.

Mr. C. Umney, of the firm of Wright, Layman, and Umney, wholesale chemists, Southwark-street, London, said that the Act of 1875 had done excellent service, and had raised the standard of purity, which at the present time was in a very good position. In his opinion the drugs in this country were not to be excelled in purity, and he attributed this largely to the working of the Act. He thought the provisions of the Act had been carried out with moderation on the part of local authorities and with very great efficiency on the part of public analysts. He admitted that very often public analysts had been called upon to undertake duties which they should not have been asked to do, and very often, owing to the absence of standards in books of reference, they had misled the public authorities. In this connexion he suggested that the standards of the British Pharmacopœia should be made statute law, and as such used by the public analysts.

The Committee then adjourned.

BOOKS ETC. RECEIVED.

ALIGHIERI, DANTE, Roma.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

AGNEW, T. H., L.R.C.S. & P. Edin., has been appointed House Physician to the Royal Infirmary, Liverpool.

ARMSTRONG, HUBERT, M.B., Ch.B. Vict., has been appointed House Surgeon to the Royal Infirmary, Liverpool.

BICKERTON, R. E., M.B., Ch.B. Vict., has been appointed House Physician and Ophthalmic Assistant to the Royal Infirmary, Liverpool.

BINNEY, E. H., M.B. & Ch.M. (Sydney), has been appointed Senior Resident Medical Officer to the Sydney Hospital, N.S.W.

BRICKWELL, H. T., M.R.C.S., L.S.A., has been appointed Medical Officer for the Chigwell Sanitary District of the Epping Union, vice Jameson, resigned.

BRADFORD, R. D., L.R.C.P., L.R.C.S., L.M. Edin., has been appointed Medical Officer for the Aldro Sanitary District of the Skirlaugh Union, vice Readman, resigned.

BROWN, F. S., M.R.C.S., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Causton and Elston Sanitary Districts of the Southwell Union.

BUCHANAN, G. S., B.Sc. Lond., M.D. (State Med.), has been appointed Medical Inspector to the Local Government Board.

COLLINS, A. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., L.M., has been appointed Medical Officer for the Riseley Sanitary District of the Bedford Union, vice Banks, resigned.

DOHIE, WM., M.D. St. AND., L.R.C.P., L.R.C.S. Edin., has been appointed Honorary Medical Officer of the Keighley Mission to the Deaf and Dumb.

DREAPER, J. B., L.R.C.P., L.M. Edin., M.R.C.S., has been appointed Medical Officer of Health for the Ashbourne Rural Sanitary District.

ELKINS, F. A., M.D. Edin., C.M., has been appointed Medical Superintendent of the Sunderland Borough Asylum for Lunatics at Ryhope.

FINNIE, J. E., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Lock Hospital, Liverpool.

GREER, THOS., M.D., M.Ch. Irel., has been appointed Medical Officer for the Second Sanitary District of the Cambridge Union, vice Rygate, resigned.

GRIFFITHS, G. B., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Surgeon in H.M.'s Prison Service.

HARTLEY, A. C., M.D., C.M., F.R.C.S. Edin., has been appointed Medical Officer for the Bedford and Kempston Sanitary District of the Bedford Union, vice Adams.

JESSOP, J. W., L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon-Lieutenant to the G. (Horncastle) Company of Rifle Volunteers.

MORRISON, J., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Resident Medical Officer to the Queen Charlotte's Lying-in Hospital.

ODELL, ROBT., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Hertford Union, vice Wylie, resigned.

ROSS, S. J., M.B., Ch.B. Vict., has been appointed House Surgeon to the Royal Infirmary, Liverpool.

RUNDLE, F. C., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Southwick Sanitary District of the Fareham Union, vice Matthews, resigned.

SCATTERY, W., M.B., C.M. Aberd., has been appointed Honorary Medical Officer of the Keighley Mission to the Deaf and Dumb.

SMALLWOOD, ED., L.S.A., has been appointed House Physician to the Royal Infirmary, Liverpool.

THORNE, A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Stock Exchange, London.

TOMORY, J. KAY, M.B., C.M. Edin., has been appointed Public Vaccinator for the Parish of Halkirk.

WHITEHEAD, A. MEREDITH, M.B., C.M. Aberd., M.R.C.S. Eng., has been appointed Honorary Surgeon to the Wellington Hospital, New Zealand.

WILKINSON, J. HOWARD, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed an Honorary Surgeon to the Dudley Dispensary.

WILSON, H. R., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Royal Infirmary, Liverpool.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASYLUMS COMMITTEE OF THE LONDON COUNTY COUNCIL.—Pathologist to the London County Asylums. Salary £700 per annum, with travelling expenses. Applications to the Clerk of the Committee, Office, 21, Whitehall-place, S.W.

BOARD OF WORKS FOR THE HOLBORN DISTRICT (IN THE COUNTY OF LONDON).—Medical Officer of Health for the Holborn District. Salary £350 per annum. Applications to the Clerk to the Board, Holborn Town Hall, London, W.C.

BRIGHTON AND HOVE LYING-IN INSTITUTION AND HOSPITAL FOR WOMEN.—House Surgeon, unmarried. Salary £80 per annum, with furnished quarters, board, gas, coals, and attendance.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Board, residence, and allowance for washing provided. Applications to the Secretary, Office, 24, Finsbury-circus, E.C.

DURHAM COUNTY ASYLUM, Durham.—Pathologist and Junior Medical Officer. Salary £100 per annum, with board.

GLAMORGAN COUNTY ASYLUM, Bridgend.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board (no beer or wine), lodging, washing, and attendance.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London, W.—Senior Clinical Assistants.

HOSPITAL FOR SICK CHILDREN, Newcastle-upon-Tyne.—Resident Medical Officer. Salary £60, with board, lodging, and laundry.

LIVERPOOL STANLEY HOSPITAL.—Honorary Assistant Surgeon.—Junior House Surgeon. Salary £70, with board, &c.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (ALBANY MEMORIAL), Queen-square, Bloomsbury.—Senior and Junior House Physician respectively. Salary of the former £100 per annum, and of the latter £50 per annum, with board and apartments, in each case, in the Hospital.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—House Physician for six months. Salary at the rate of £60 per annum.

ROYAL EAR HOSPITAL, Frith-street, Scho-square, London, W.—House Surgeon (non-resident) for six months. Honorarium £12 10s.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, London.—Two Examiners in Dental Surgery.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo Bridge-road, London, S.E.—Clinical Assistant and Anaesthetist for six months. Salary at the rate of £30 per annum.

RURAL DISTRICT COUNCIL OF DROXFORD.—Medical Officer of Health for this rural district. Salary £125 per annum, to include travelling and all other expenses. Applications to the Clerk, Bishop's Waltham.

ST. LUKE'S HOSPITAL, London, E.C.—Clinical Assistant for six months. Board and residence provided.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Lecturer on Mental Diseases.

SOMERSET AND BATH LUNATIC ASYLUM, Wells, Somerset.—Second Assistant Medical Officer, unmarried. Salary £100 a year, with board, lodging, and washing.

TRINITY COLLEGE, Dublin.—Lecturer in Pathology.

UNIVERSITY COLLEGE, London.—Professorship of Materia Medica and Therapeutics.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician and House Surgeon for six months. Board and lodging provided.

Births, Marriages, and Deaths.

BIRTHS.

COOK.—On May 13th, at "Byfield," Bromley, Kent, the wife of P. Inkerman Cook, M.D., of a son.

COWELL.—On May 14th, at Tanza-road, Hampstead, the wife of A. R. Cowell, M.A., M.B. Cantab., of a daughter.

FOOT.—On May 19th, at Church House, Pulborough, Sussex, the wife of Ernest Foot, M.R.C.S., L.S.A., of a son.

GARDENER.—On May 18th, at Darley House, Venner-road, Sydenham, the wife of William F. Gardener, M.R.C.S., of a son.

GODDARD.—On May 18th, the wife of Bertram Goddard, L.R.C.P. Lond., M.R.C.S. Eng., of Pentonville-road, of a son.

HAY.—On May 20th, at Lichfield, Stafford, the wife of Deputy-Inspector-General Robert Hay, R.N., of a son.

KENYON.—On May 15th, at Oakhurst, London-road, St. Leonards-on-Sea, the wife of G. Herbert Kenyon, M.D., late of Hooton Pagnell, of a daughter.

KINGSTON.—On May 20th, at Alsager, Stoke-on-Trent, the wife of Henry F. Kingston, B.A., M.B., B.Ch. Dub., of a daughter.

MACLEAN.—On May 20th, at Penrose Lodge, Tooting, the wife of J. N. Maclean, M.B., of a son.

POWELL.—On May 16th, at Ashwick Court, Oakhill, Bath, the wife of Lewis Powell, M.R.C.S., of a daughter.

TAYLOR.—On May 19th, at Kennington-park-road, S.E., the wife of Herbert Taylor, M.B., of a son.

WEBSTER.—On May 19th, at Duppas-hill, Croydon, the wife of George L. Webster, M.R.C.S. Eng., of a daughter.

MARRIAGE.

BLAIKIE—LEICESTER.—On May 21st, at St. Thomas's English Episcopal Church, Edinburgh, Robert Henry Blaikie, M.A., M.D., F.R.C.S. Edin., fourth son of the Rev. Professor W. Garden Blaikie, D.D., LL.D., New College, Edinburgh, to Edith, second daughter of the Rev. M. A. Leicester, M.A. Cantab., Dalhousieterrace, Edinburgh.

DEATHS.

BOSTOCK.—On May 18th, at Onslow-garlands, Deputy-Surgeon-General John Ashton Bostock, C.B., Hon. Surgeon to the Queen, late Scots Guards, in his 80th year.

CLEGHORN.—On May 16th, at Stravithie, Fifeshire, Hugh Francis Clarke Cleghorn, M.D., LL.D., in his 75th year.

CRAIGIE.—At Musselburgh, on the 16th inst., James Stedman Craigie, M.D. Edin., B.Sc. Pub. Health Edin., aged 40.

MARSTON.—On May 16th, drowned at sea off Shoeburyness from the sinking of a yacht during a squall, Lieutenant Frederick Muir Marston, Royal Artillery, son of Surgeon-General and Mrs. Jeffery A. Marston.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Hyslop: Puerperal and Lactational Insanity.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular in question.

THE CARE OF YOUNG IMBECILES.

A CORRESPONDENT sends us the following, and would be glad to know where and to whom to apply in order to assist the subjoined case, on which we comment in another column:—

"There is in the village here a labouring man who is unfortunately the father of a girl aged five years, who from her birth has been, and continues to be, an idiot of the lowest type—cannot walk now talk, is incurable, and has not even sufficient intelligence to restrain the calls of nature. The parents are hardworking, honest people. They have several other children and a very old woman living with and dependent on them. The mother of the child has hitherto done her utmost for the idiot; but now, being in rather delicate health, she finds the strain almost more than she can bear. The painful sight is also distressing and most injurious to the other children. I am unable to discover an asylum or institution where the case can be admitted."

Mr. E. S. E. Hever (St. Bartholomew's Hospital).—The name was not received in the official list.

A PROTEST.

To the Editors of THE LANCET.

SIRS,—On looking over the column of vacancies in THE LANCET of May 11th I saw an advertisement for an assistant surgeon as locum tenens for three months at the Rainhill County Lunatic Asylum, near Liverpool, and the inducement held out is £2 2s., with board and lodging, per month. I had the honour of serving as alderman from the formation of the county council in 1888 till 1892, and only wish that I had remained a member of that body so as to have meted out punishment to the party who dared to offer 10s. 6d. per week to a registered member of what is supposed to be a learned profession.

I am, Sirs, yours faithfully,

A LATE ALDERMAN OF THE LANCASHIRE COUNTY COUNCIL.
May 13th, 1896.

TROOPS FOR INDIA *via* THE CAPE.

A CORRESPONDENT writes from Croydon advocating very strongly the Cape route, and urges the expediency of the establishment of a midway sanatorium there, and the disembarkation and re-embarkation of troops at the Cape of Good Hope. While we fully allow many of the advantages that can be urged in favour of the Cape climate and the importance of maintaining that route to India, we do not think that there is much prospect, on account of financial and other considerations, of our correspondent's views being entertained by the Governments of India and this country. The troopship service *via* the Suez Canal has been arranged, as far as practicable, so as to avoid invalids from India arriving at the commencement of winter in this climate. As a rule, soldiers—especially sick soldiers—are very anxious to get home on leaving India, and do not like to be detained anywhere *en route*, even for hygienic reasons. One great thing which should never be lost sight of is the importance of quartering troops arriving from abroad in the most suitable and least exposed stations that can be found for them in this country during the following winter and spring.

Ajaz.—We are of opinion that in such cases the duty of the neighbour summoned in an emergency to the patient of another medical man is to do what is necessary and hand the case over to the regular medical attendant.

"A CASE FOR DIAGNOSIS."

To the Editors of THE LANCET.

SIRS,—I beg to thank Dr. Oscar Jennings and "M.B. Edin." for their courtesy in replying to my letter. The case under discussion occurred in the person of an inmate of my house, so that I feel sure that we may put on one side the possibility of cocaine poisoning; and as the patient has never been abroad or had an attack of ague this cannot have been the cause. There are two rather important facts I have omitted to mention—viz., (1) the patient at the time of the attack was adjusting the vaginal tube preparatory to a douche of a solution of boro-glyceride, using a soft red rubber tube perforated only at the sides; and (2) forty-eight hours after the commencement of the attack a cough occurred and became quite troublesome. No expectoration was seen, or came up, but after a cough the patient complained of a very putrid taste at times. The cough lasted about ten days. Looking at the symptoms, I am now inclined to think that a small embolism must have become impacted in a branch of the pulmonary artery, and possibly a thrombus formed in connexion with it, the result being also a pulmonary infarct. I shall be glad if any reader of THE LANCET will give me his opinion as to the correctness of my surmise. I am, Sirs, yours truly,

May 19th, 1895.

M.D. EDIN.

THE CASE OF MR. C. B. TOWNSEND.

THE following additional subscriptions have been received or promised, and are hereby gratefully acknowledged:—

Dr. Jas. Chapman (Southampton) ...	£1 1 0	Mr. Arthur S. Wills (Stafford) ...	£0 10 0
